Received 27 January 1986

**Abstract.** Using the numerical results of the finite-size scaling study of the  $q$ -state Potts model by Blöte and Nightingale, we obtain the following conjectured expressions for the universal amplitude of the free energy density:

$$A_0(u) = \pi \frac{(2 - 3u)(u + 1)}{6(2 - u)}$$

where

$$0 \leq u \equiv \frac{2}{\pi} \cos^{-1} \left( \frac{\sqrt{q}}{2} \right) \leq 1.$$

According to Privman and Fisher (1984), the singular part of the free energy density on a cylinder-shaped system with size  $V = L^{d-1} \times \infty$  near the critical point  $t = 0$ ,  $h = 0$  ( $t = (T - T_c)/T_c$ ,  $h = H/k_B T$ ) may be written as

$$f^{(s)}(t, h, L) = -\frac{F^{(s)}}{V k_B T} \simeq L^{-d} Y(x_1, x_2) \quad x_1 = C_1 t L^{y_t} \quad x_2 = C_2 h L^{y_h} \quad (1)$$

where  $Y(x, y)$  is a universal function,  $y_t$  and  $y_h$  are the thermal and magnetic exponents.  $C_1$  and  $C_2$  are non-universal metric factors.

In two dimensions, on a  $L \times \infty$  strip with periodic boundary conditions built up of  $L \times l$  slices, the free energy density is given by

$$f_0(t, h, L) = (1/lL) \ln \Lambda_0(t, h, L) \quad (2)$$

where  $\Lambda_0$  is the largest eigenvalue of the transfer matrix. Free energy levels  $f_j(t, h, L)$  may be defined using the subdominant eigenvalues  $\Lambda_j$  of the transfer matrix ( $\Lambda_0 > \Lambda_1 \geq \Lambda_2 \dots$ ) through

$$f_j(t, h, L) = (1/lL) \ln \Lambda_j(t, h, L). \quad (3)$$

† Laboratoire associé au CNRS no 155.

**Table 1.** Free energy density at the critical point in the  $q$ -state Potts model as a function of the strip width  $L$  (data taken from Blöte and Nightingale 1982). The values converge towards the exact result  $B$  (Baxter 1973) for the infinite system.

1.05	1.415 741 452 203	1.415 699 494 189	1.415 668 519 467	1.415 521 797 633
3	2.075 404 683 689	2.074 406 246 134	2.073 669 695 186	2.070 187 162 577
4	2.266 084 394 071	2.264 826 740 710	2.263 899 533 697	2.259 524 751 387

The singular part of the free energy levels is expected to behave as in equation (1):

$$f_j^{(s)}(t, h, L) \simeq L^{-2} Y_j(x_1, x_2). \quad (4)$$

The singular part is defined as

$$f_j(t, h, L) = f_j^{(s)}(t, h, L) + f_\infty(t, h) \quad (5)$$

where the last term is the analytic background which is the same for all the levels.

At the critical point one obtains

$$f_j = A_j L^{-2} + B \quad (6)$$

where  $A_j = Y_j(0, 0)$  is a universal amplitude and  $B$  is the critical value of the free energy density in the infinite system.

The correlation lengths are given by

$$\xi_{\parallel j}(t, h, L) = l \left[ \ln \left( \frac{\Lambda_0}{\Lambda_j} \right) \right]^{-1} \quad (7)$$

( $j = 1$ : spin-spin correlations,  $j = 2$ : energy-energy correlations) so that, using equations (3) and (6), one obtains

$$\xi_{\parallel j}(0, 0, L) = S_j L \quad (8)$$

where

$$S_j = (A_0 - A_j)^{-1}. \quad (9)$$

These correlation length universal amplitudes  $S_j$  are known to be related to the decay exponents  $\eta_j$  (Pichard and Sarma 1981, Luck 1982, Derrida and de Sèze 1982, Nightingale and Blöte 1983, Cardy 1984) through

$$S_j = 1/\pi\eta_j \quad (10)$$

so that

$$A_0 - A_j = \pi\eta_j. \quad (11)$$

**Table 2.** Universal amplitude  $A_0$  extrap obtained through a three-point fit of  $A_0(L)$  using equation (12).

In this letter, we deduce the universal amplitude of the free energy density  $A_0$  from the results of a finite-size scaling study (Blöte and Nightingale 1982). A simple analytic expression is conjectured which is in excellent agreement with the numerical results and reproduces the known exact value  $A_0 = \pi/12$  in the Ising case,  $q = 2$  (Ferdinand and Fisher 1969).

Using the exact values for  $B$  (Baxter 1973) and  $f_0(L)$  for the three largest strips shown in table 1, the universal amplitude  $A_0(L)$  are obtained. A three-point fit is used to estimate  $A_0$ , assuming a power law correction to scaling

$$A_0(L) = A_0 + CL^{-y}. \quad (12)$$

The results are shown in table 2.

The exponents of the  $q$ -state Potts model are exactly known (den Nijs 1979, Black and Emery 1981, Nienhuis *et al* 1980, Pearson 1980, Wu 1982). Using the variable  $u$  defined as

$$0 \leq u \equiv (2/\pi) \cos^{-1}(\sqrt{q}/2) \leq 1 \quad (13)$$

one has

$$\begin{aligned} y_t &= 3(1-u)/(2-u) \quad q \leq 4 \\ y_h &= (3-u)(5-u)/4(2-u) \end{aligned} \quad (14)$$

and the decay exponents for the spin-spin and energy-energy correlation functions are

$$\begin{aligned} \eta &= \frac{1-u^2}{2(2-u)} \\ \eta_{ee} &= \frac{2(1+u)}{2-u}. \end{aligned} \quad (15)$$

The numerical results obtained for  $A_0$  may be fitted using the following expression (table 3):

$$A_0 = \pi \frac{(2-3u)(u+1)}{6(2-u)}. \quad (16)$$

The universal amplitudes for the second and third levels follow from equations (11) and (15):

$$\begin{aligned} A_1 &= -\pi \frac{1+u}{6(2-u)} \\ A_2 &= -\pi \frac{(1+u)(10+3u)}{6(2-u)}. \end{aligned} \quad (17)$$

*Note added.* After this letter was submitted for publication, we learnt that the result given in equation (16) had been independently conjectured and derived from conformal invariance by Blöte *et al* (1986) (see also Affleck 1986).
