Abstract

Using exact partition functions and finite-size corrections for the Ising model on finite square, plane triangular, and honeycomb lattices, we obtain universal finite-size scaling functions for the specific heat, the internal energy, and the free energy of the Ising model on these lattices with exact non-universal metric factors.

PACS numbers: 05.50.+q, 75.10.-b

Finite-size scaling has been of interest to scientists working on a variety of critical systems or problems, including superfluid, spin models, percolation models, lattice gauge models, spin glass, metastability, etc [1–6]. Universal finite-size scaling and finite-size corrections in finite critical systems have attracted much attention in recent decades [2–11]. Using renormalization group (RG) arguments, in 1984 Privman and Fisher first proposed the concepts of universal finite-size scaling functions (UFSSF's) and non-universal metric factors [2]. Using Monte Carlo methods [12] and choosing aspect ratios of the square (sq), plane triangular (pt), and honeycomb (hc) lattices so that they have the relative proportions $1:\sqrt{3}/2:\sqrt{3}$ [13], Hu, Okabe, *et al.* found UFSSF's for the percolation and the Ising models on two-dimensional lattices [5, 6]. Since these studies were based on numerical simulations, there are always some numerical uncertainty in the obtained results. Here we use the exact partition functions of the Ising model on finite sq, pt and hc lattices with periodic-aperiodic boundary conditions [14, 15] and an exact expansion method [10] to obtain exact finite-size corrections of the free energy f^B , the internal energy E^B , and the specific heat C^B of the critical Ising model on these lattices with periodic-periodic (pp), periodic-antiperiodic (pa), antiperiodic-periodic (ap) and antiperiodic-antiperiodic (aa) boundary conditions, where B denotes boundary conditions. Using these coefficients and extend a method [16] to subtract leading singular term from the free energy, we subtract leading singular terms from C^B , E^B , and f^B and find that the corresponding residuals Δ^B , Γ^B , and W^B (see Eqs.(7)-(9) below), have very good finite-size scaling behavior. Choosing aspect ratios of the sq, pt, and hc lattices so that they have the relative proportions $1:\sqrt{3}/2:\sqrt{3}$ [13] and calculating exact non-universal metric factors from exact partition functions and finite-size corrections for the Ising model, we find that Δ^B , Γ^B , and W^B of the sq, pt, and hc lattices have very nice universal finite-size scaling behavior.

The partition function of the Ising model is given by

$$Z = \sum_{\{\sigma\}} \exp[\beta J \sum_{\langle ij \rangle} \sigma_i \sigma_j], \tag{1}$$

where J is the coupling constant of the Ising spin, $\beta = 1/(k_B T)$ with k_B being the Boltzmann constant and T being the absolute temperature, $\sigma_i = \pm 1$ is the Ising spin at site *i*, the first sum is over all spin states, and the second sum is over the nearest-neighbor (NN) pairs $\langle i, j \rangle$ of the Ising spins. In this Letter, the geometric structures of the sq, pt and hc lattices follow those in [13]. The exact partition functions for $L_1 \times L_2$ sq, pt and hc lattices

\mathbf{pt}	1	$\left(1+t^2\right)^3+8t^3$	$2t\left(1-t^2 ight)^2$	$2t\left(1-t^2 ight)^2$	$\frac{1}{2}\ln\sqrt{3}$
hc	$\frac{1}{2}$	$1+3t^4$	$2t^2\left(1-t^2 ight)$	$2t^2\left(1-t^2 ight)$	$\frac{1}{2}\ln\left(2+\sqrt{3}\right)$

for periodic-aperiodic boundary conditions have been found to be [15]

$$Z^{B} = \frac{1}{2} 2^{L_{1}L_{2}} \left[\cosh\left(\beta J\right) \right]^{zL_{1}L_{2}/2} \sum_{i=1}^{4} \varepsilon_{i}^{B} \Omega_{i},$$
(2)

where z is the coordination number of the lattice and ε_i^B shown in Table I are sign factors specified by boundary conditions (BC's), and $\Omega_1 = \Omega_{\frac{1}{2}\frac{1}{2}}, \ \Omega_2 = \Omega_{\frac{1}{2}0}, \ \Omega_3 = \Omega_{0\frac{1}{2}}, \ \Omega_4 = -\text{sgn}\left(\frac{\theta-\theta_c}{\theta_c}\right)\Omega_{00}$, with

$$\Omega_{\mu\nu} = \prod_{p=0}^{gL_1 - 1} \prod_{q=0}^{L_2 - 1} \left\{ A_0 - A_1 \left[\cos \frac{2\pi(p+\mu)}{gL_1} + \cos \frac{2\pi(q+\nu)}{L_2} \right] - A_2 \cos \left(\frac{2\pi(p+\mu)}{gL_1} - \frac{2\pi(q+\nu)}{L_2} \right) \right\}^{1/2}.$$
 (3)

The values of g, the explicit forms of A_0 , A_1 and A_2 , and the critical values of βJ , $\beta_c J$, are listed in Table II.

To calculate the specific heat, we write Z^B as

$$Z^{B} = \frac{1}{2} \left[2\sinh(2\eta) \right]^{L_{1}L_{2}/2} \sum_{i=1}^{4} \varepsilon_{i}^{B} Z_{i} \left(\tau, R, L\right),$$
(4)

where $\eta = \beta J$, $Z_i(\tau, R, L) = \Omega_i / (A_1/2)^{gL_1L_2/2}$, $\tau = D_2L\epsilon$, D_2 is a non-universal metric factor [17], $L = (L_1L_2)^{1/2}$ is the characteristic size of the lattice, $\epsilon = (T - T_c) / T_c$ is the reduced temperature and $R = L_1/L_2$ is the aspect ratio. Then, the specific heat

TABLE III: Expressions for $c_{0,0}$, $c_{0,1}$, $c_{0,2}$, c_1 , $a_{0,0}$, a_0 , a_1 , q, and $E_{0,0}$; $\gamma_E (= 0.5772156649...)$ is the Euler constant.

 $C^B/k_B \equiv (\eta^2/L^2) \left(\partial^2 \ln Z^B/\partial \eta^2\right)$ near $\tau = 0$ can be written as

$$\frac{C^B}{k_B} = \left[C_{0,0} \ln L + C_0^B(R) + \frac{C_1^B(R)}{L} + O\left(\frac{1}{L^2}\right) \right]
+ \frac{1}{D_2} \left[A_0^B(R) + \frac{A_{0,0}(R)}{L} \ln L + O\left(\frac{1}{L}\right) \right] \tau + O\left(\tau^2\right),$$
(5)

Here $C_{0,0} = c_{0,0}\eta_c^2$, $C_0^B(R) = \eta_c^2[c_{0,1} - 2c_{0,0}f_1 - c_{0,2}Rf_2^2 - \frac{1}{2}c_{0,0}\ln R]$, $C_1^B(R) = -c_1\sqrt{R}\eta_c^2f_2$, $A_{0,0}(R) = a_{0,0}\sqrt{R}\eta_c^3 - 2c_{0,0}\eta_c^2$, $A_0^B(R) = -\frac{a_0\sqrt{R}\eta_c^3}{\pi}f_2[\pi Rf_2^2 + a_1f_1 - \frac{1}{3}a_1f_3]$, where $\eta_c = \beta_c J$, $f_1 = (\varepsilon_1^B |\theta_3| \ln |\theta_3| + \varepsilon_3^B |\theta_4| \ln |\theta_4| + \varepsilon_2^B |\theta_2| \ln |\theta_2|)/F$, $f_2 = (\varepsilon_4^B |\theta_2| |\theta_3| |\theta_4|)/F$, $f_3 = \ln (4 |\theta_2| |\theta_3| |\theta_4|)$, $F = (\varepsilon_1^B |\theta_3| + \varepsilon_3^B |\theta_4| + \varepsilon_2^B |\theta_2|)$, with $\theta_i = \theta_i (0, q)$ the Elliptic theta functions of modulus q. Expressions for $c_{0,0}, c_{0,1}, c_{0,2}, c_1, a_{0,0}, a_0, a_1$, and q are listed in Table III.

Based on [16], we write the free energy $f^B \equiv (1/L^2) \ln Z^B$ near $\epsilon = 0$ as

$$f^{B} \approx F_{0}^{B} + F_{1}^{B}\epsilon - \frac{1}{2} \left[C_{0}^{B}(R) + C_{0,0} \ln L \right] \epsilon^{2} - (D_{2}L)^{-2} W^{B}(\tau, R, L) , \qquad (6)$$

with scaling function W^B . Here $F_0^B = f_{0,0} + f_{0,1}/L^2 + O(L^{-4})$ and $F_1^B = \beta_c E_{0,0} + \beta_c E_{0,1}/L + O(L^{-2})$, where $f_{0,0} = 0.9296954...$ for sq, 0.8795854... for pt, and 1.0250591... for hc lattices, $f_{0,1}^B = \ln F - \frac{1}{3} \ln f_3$, $E_{0,0}$ for the sq, pt and hc lattices are listed in Table III, and $E_{0,1}^B = -\sqrt{c_{0,2}R}f_2$.

To study finite-size scaling, we define the scaling function for the specific heat, Δ^B , as

$$\Delta^{B} (\tau, R, L) = \frac{\partial^{2} W^{B}(\tau, R, L)}{\partial \tau^{2}} = \frac{c^{B}}{k_{B}} - \left[C_{0}^{B}(R) + C_{0,0} \ln L\right]$$
$$= \frac{1}{D_{2}} \left[A_{0}^{B}(R) + \frac{A_{0,0}(R)}{L} \ln L + O\left(\frac{1}{L}\right)\right] \tau + O\left(\tau^{2}\right) + \frac{C_{1}^{B}(R)}{L} + O\left(\frac{1}{L^{2}}\right). \quad (7)$$

According to the definition of internal energy $E^B = -(1/L^2) \left(\partial \ln Z^B\right) / (\partial \eta)$, we define the

scaling function for the internal energy, Γ^B , as

$$\Gamma^{B}(\tau, R, L) = \frac{\partial W^{B}(\tau, R, L)}{\partial \tau} = -D_{2}L\beta_{c}\left\{E^{B} - \left(E_{0,0} + \frac{E_{0,1}^{B}}{L}\right) + \frac{1}{\beta_{c}}\left[C_{0}^{B}(R) + C_{0,0}\ln L\right]\epsilon\right\}$$
$$\simeq \Delta^{B}\tau + O\left(\tau^{2}\right). \tag{8}$$

Similarly, the scaling function for the free energy, W^B , is

$$W^{B}(\tau, R, L) = -(D_{2}L)^{2} \left\{ \frac{\beta_{c}}{\beta} \left[f^{B} - \left(f_{0,0} + \frac{f_{0,1}^{B}}{L^{2}} \right) \right] + \beta_{c} \left(E_{0,0} + \frac{E_{0,1}}{L} \right) \epsilon + \frac{1}{2} \left[C_{0}^{B}(R) + C_{0,0} \ln L \right] \epsilon^{2} \right\}$$
$$\simeq \frac{1}{2} \Delta^{B} \tau^{2} + O(\tau^{3}).$$
(9)

In the scaling function Δ^B , $C_1^B(R)$ is the leading term in finite-size corrections, and can be used to interpret the finite-size effects of the lattice systems. From this aspect, the finite-size effect for the pp boundary condition is the smallest in comparison with the pa, ap and aa boundaries. The behaviors of $\Delta^B(\tau, R = 1, L)$, $\Gamma^B(\tau, R = 1, L)$ and $W^B(\tau, R = 1, L)$ as a function of τ with $D_2 = 1$ for the sq, pt and hc lattices with periodic boundary conditions are shown in Figs.1(a), (b) and (c), respectively, which show that these quantities have very nice finite-size scaling behavior. We note that, for isotropic coupling, $\Delta_{\rm sq}^{\rm pa}(\tau, R = 1, L) = \Delta_{\rm sq}^{\rm ap}(\tau, R = 1, L)$ for the sq lattice, and $\Delta_{\rm pt}^{\rm pa}(\tau, R = 1, L) =$ $\Delta_{\rm pt}^{\rm ap}(\tau, R = 1, L) = \Delta_{\rm pt}^{\rm aa}(\tau, R = 1, L)$ for the pt lattice, due to their symmetric structures. However, $g \neq 1$ for the hc lattice violates the symmetry by exchanging L_1 and L_2 when R = 1, and $\Delta_{\rm pt}^{\rm pa}(\tau, R = 1, L) \neq \Delta_{\rm pt}^{\rm ap}(\tau, R = 1, L) \neq \Delta_{\rm pt}^{\rm ap}(\tau, R = 1, L)$.

To study the UFSSF's of $\Delta^B(\tau, R, L)$, we take aspect ratios of the sq, pt and hc lattices to have the relative proportions $1:\sqrt{3}/2:\sqrt{3}$. Equation (7) implies that for large lattices, the slope of Δ^B as a function of τ at $\tau = 0$ is determined by A_0^B . We can further multiply the scaling function by another non-universal metric factor D_1 to obtain

$$D_{1}\Delta^{B}(\tau, R, L) = \frac{D_{1}}{D_{2}} \left[A_{0}^{B}(R) + \frac{A_{0,0}(R)}{L} \ln L + O\left(\frac{1}{L}\right) \right] \tau + O\left(\tau^{2}\right) + O\left(\frac{1}{L}\right).$$
(10)

We can take values of D_1/D_2 so that the leading terms in the right hand sides of (10) have the same slope for sq, pt, and hc lattices. Accordingly, we take the values of D_1/D_2 as $(D_1/D_2)_{sq}=1$ for the sq lattice, $(D_1/D_2)_{pt} = A^B_{0,sq}(R_{sq})/A^B_{0,pt}(R_{pt})$ for the pt lattice and $(D_1/D_2)_{hc} = A^B_{0,sq}(R_{sq})/A^B_{0,hc}(R_{hc})$ for the hc lattice. To explore the behaviors of the

amplitude A_0^B as a function of the aspect ratio R, we consider $A_0^B(D_3R)$ with scale factors $D_3 = 1, \sqrt{3}/2, \sqrt{3}$ for the sq, pt and hc lattices, respectively. The sign of the $A_0^B(D_3R)$, in general, gives the information about the location (τ_{\max}) of the maximum of the specific heat. When $A_0^B(D_3R)$ is positive, $\tau_{\max} > \tau_c = 0$, and when $A_0^B(D_3R)$ is negative, $\tau_{\max} < \tau_c$. For the pp and pa boundary conditions, the behaviors of $A_0^B(D_3R)$ for the sq, pt and hc lattices are roughly in a similar feature in the region of $0 < R \leq 1$. However, for the ap and aa boundary conditions, the curves of $A_0^B(D_3R)$ for sq lattice are quite different from those for pt and hc lattices.

To show examples of (D_1/D_2) and UFSSF's, we note that for R = 1, $(D_1/D_2)_{pt} = 0.9688...(pp)$, 1.0297...(pa), and $(D_1/D_2)_{hc} = 1.0332...(pp)$, 1.0981...(pa). For R = 1/2 and 1/3, we have $(D_1/D_2)_{pt} = 0.9864...(pp)$, 0.9864...(pa), and $(D_1/D_2)_{hc} = 1.0520...(pp)$, 1.0520...(pa). We find that the values of D_1/D_2 are roughly 0.9864..., 1.0520... (pp), 1.0520...(pa). We find that the values of D_1/D_2 are roughly 0.9864..., 1.0520... (pp), and pa boundary conditions. Using these values and calculating D_1 based on exact specific heat for such finite lattices, we plot the $D_1\Delta^B(\tau, D_3R, L)$ for the sq, pt and hc lattices in Figs.2(a), (b) and (c), which show that the residual specific heats have very nice universal finite-size scaling functions of the internal energy and the free energy by the same non-universal metric factor D_1 , and obtain the universal scaling functions for $D_1\Gamma^B(\tau, D_3R, L)$ and $D_1W^B(\tau, D_3R, L)$, which are plotted in Figs.3(a), (b) and (c). These figures also show very nice universal finite-size scaling behavior.

Although the results of this Letter are based on analytic expressions for the physical quantities of the Ising model, our formulations can be extended to numerical or experimental studies of critical finite systems [18]. For example, the coefficients $C_0^B(R)$ and $C_{0,0}$ of Eq. (7) can be evaluated by using extrapolation techniques to analyze simulation or experimental data, then one can define the scaling function of the specific heat similar to that in Eq.(7). As a result, the UFSSF for the specific heat can be obtained.

We thank H. W. J. Bloete for a critical reading. This work was supported in part by the National Science Council of the Republic of China (Taiwan) under Grant No. NSC 91-2112-M-001-056.
