**Abstract.** We investigate the  $\cos 2\phi$  azimuthal asymmetry in Drell–Yan and  $J/\psi$  production from unpolarized  $p\bar{p}$  scattering at GSI-HESR energies. The contribution to this asymmetry arising from the leading-twist Boer-Mulders function  $h_1^{\perp}(x, \mathbf{k}_T^2)$ , which describes a correlation between the transverse momentum and the transverse spin of quarks in an unpolarized hadron, is explicitly evaluated, and predictions for the GSI-HESR kinematic regime are presented. We show that the  $\cos 2\phi$  asymmetry is quite sizable both on the  $J/\psi$  peak and in the Drell-Yan continuum region. Therefore these processes may offer an experimentally viable access to the Boer-Mulders function in the early unpolarized stage of GSI experiments.

Key words. Azimuthal asymmetries – Drell-Yan process – transverse spin –  $k_T$ -dependent distributions

## 1 Introduction

The spin structure of hadrons is under intense investigation, both theoretically and experimentally. In hadronhadron scattering one would naively speculate that the polarization of at least one of the incoming hadrons, the beam or the target, or of both, is needed in order to investigate the spin properties of hadrons. However this is not the case if one takes into account the intrinsic momentum of partons. It is known in fact that there is a new kind of leading-twist transverse-momentum dependent distribution function, the so called Boer–Mulders function  $h_{\perp}^{\perp}(x, \mathbf{k}_T^2)$  [1,2], which describes the transversity of quarks inside an unpolarized hadron. This new function, which is chirally odd, manifests itself through the coupling to another chiral-odd quantity, such as the transversity distribution  $h_1$ , the Collins function  $H_1^{\perp}$ , or another Boer-Mulders function [3]. Therefore the spin structure of hadrons can be also studied in physical processes without beam and/or target polarization. It has been argued by Boer [2] that  $h_{\perp}^{\perp}(x, \mathbf{k}_T^2)$  can account for the large  $\cos 2\phi$ azimuthal asymmetry observed in the unpolarized pionnucleon Drell-Yan process [4,5]. The origin of  $h_1^{\perp}(x, \mathbf{k}_T^2)$ has been addressed in Refs. [6,7]. The first calculation of  $h_1^{\perp}(x, \mathbf{k}_T^2)$ , in a quark-scalar diquark model, was reported by Goldstein and Gamberg [8]. Soon after this work, Boer,

Brodsky, and Hwang [9], using a similar model, showed that the analyzing power  $\nu$  of the  $\cos 2\phi$  asymmetry could be as high as 30% in the unpolarized  $p\bar{p}$  Drell-Yan process, and smaller in pp scattering. The Boer–Mulders function of the pion was calculated [10,11] in a quark–spectatorantiquark model and shown to reproduce, in combination with the corresponding distribution of the proton [12], the  $\cos 2\phi$  asymmetry in the  $\pi^- N$  Drell-Yan process measured by NA10 Collaboration [4]. The Boer-Mulders function, combined with the Collins function, can also produce the  $\cos 2\phi$  asymmetries of semi-inclusive pion leptoproduction from unpolarized nucleons [13,14].

Recently, the  $\cos 2\phi$  azimuthal asymmetry of the  $p\bar{p}$ Drell-Yan process has received much attention, as there have been proposals to study spin phenomena in polarized and unpolarized  $p\bar{p}$  scattering at the High-Energy Storage Ring (HESR) of GSI [15,16]. There have been numerical simulations [17] as well as model calculations [9, 18] of the  $\cos 2\phi$  asymmetry in the unpolarized  $p\bar{p}$  Drell-Yan process. The purpose of this paper is to investigate the  $\cos 2\phi$ asymmetry of Drell–Yan and  $J/\psi$  production in unpolarized  $p\bar{p}$  scattering, using a model of  $h_1^{\perp}(x, \mathbf{k}_T^2)$  [11,12,14] that has been adjusted to fit the NA10  $\pi^- N$  Drell-Yan data [4] and shown to be in agreement with the ZEUS [19] and EMC [20] semi-inclusive DIS data. As we will see, in the GSI kinematic domain the  $\cos 2\phi$  asymmetry turns out to be rather large. In particular, the advantage of studying the  $J/\psi$  production is that, while its  $\cos 2\phi$  asymmetry is similar in size to the corresponding asymmetry of the Drell-Yan continuum production, the counting rate on the  $J/\psi$  peak is two orders of magnitude higher compared to the region above this peak.

# **2** The $\cos 2\phi$ asymmetry in Drell-Yan and $J/\psi$ production

The Drell-Yan process represents an ideal window on the hadron structure, since it probes only parton densities. We are interested in the transverse momentum distribution of the lepton pairs, hence we have to consider the intrinsic transverse momenta of partons inside the hadrons. The non-collinear factorization theorem for Drell-Yan process has been recently proven by Ji, Ma and Yuan [21] for  $Q_T \ll Q$ .

The angular differential cross section for the unpolarized Drell-Yan process is usually parametrized as

$$\frac{1}{\sigma^{\rm DY}} \frac{d\sigma^{\rm DY}}{d\Omega} = \frac{3}{4\pi} \frac{1}{\lambda+3} \left( 1 + \lambda \cos^2 \theta + \mu \sin 2\theta \cos \phi + \frac{\nu}{2} \sin^2 \theta \cos 2\phi \right) \,. \tag{1}$$

where  $\theta$  and  $\phi$  are, respectively, the polar angle and the azimuthal angle of dileptons in the Collins–Soper frame [22]. At leading order, the  $\phi$ -independent term of the unpolarized Drell-Yan cross section for proton-antiproton collisions is

$$\frac{d\sigma_{p\bar{p}}^{\rm DY}}{d\Omega \, dx_1 \, dx_2 \, d^2 \mathbf{q}_T} = \frac{\alpha_{\rm em}^2}{12 \, M^2} (1 + \cos^2 \theta)$$
$$\times \sum_a e_a^2 \int d^2 \mathbf{k}_T \, d^2 \mathbf{p}_T \, \delta^2 (\mathbf{k}_T + \mathbf{p}_T - \mathbf{q}_T)$$
$$\times f_1^a(x_1, \mathbf{k}_T^2) f_1^a(x_2, \mathbf{p}_T^2), \tag{2}$$

where  $M^2$  is the invariant mass squared of the lepton pair and  $\mathbf{q}_T$  is the transverse momentum of the virtual photon in the frame where the two colliding hadrons are collinear. In Eq. (2) we denoted by  $f_1(x, \mathbf{k}_T^2)$  the unintegrated quark number density in the proton, and we used the fact that the antiquark distributions in the antiproton are equal to the quark distributions in the proton.

We will consider the  $\nu$  term in (1). It is known that gluon radiation processes give rise to a non-zero  $\cos 2\phi$ asymmetry, which in case of  $q\bar{q}$  annihilation dominance is given by  $\nu = Q_T^2/(M^2 + 3Q_T^2/2)$  [23]. Various quantitative analyses [24, 25, 4] show that perturbative corrections are unable to reproduce both the magnitude and the  $Q_T$ -dependence of  $\nu$  as observed by NA10 in the region  $M \sim 4-8$  GeV, but for lower M values the perturbative asymmetry might be relevant. In the present paper we will focus on the Boer–Mulders contribution to the  $\cos 2\phi$ asymmetry, which has been shown to explain the NA10 results [2] and represents a large effect in the moderate– $Q_T$ region we are interested in.<sup>1</sup> The expression for the contribution of the Boer-Mulders distribution to the unpolarized cross-section is [2]

$$\frac{d\sigma_{p\bar{p}}^{\rm DY}}{d\Omega \, dx_1 \, dx_2 \, d^2 \mathbf{q}_T} \bigg|_{\cos 2\phi} = \frac{\alpha_{\rm em}^2}{12 \, M^2} \sin^2 \theta \\
\times \sum_a e_a^2 \int d^2 \mathbf{k}_T d^2 \mathbf{p}_T \, \delta^2 (\mathbf{k}_T + \mathbf{p}_T - \mathbf{q}_T) \\
\times \frac{(2\hat{\mathbf{h}} \cdot \mathbf{k}_T \hat{\mathbf{h}} \cdot \mathbf{p}_T - \mathbf{k}_T \cdot \mathbf{p}_T)}{m_N^2} \\
\times h_1^{\perp a}(x_1, \mathbf{k}_T^2) h_1^{\perp a}(x_2, \mathbf{p}_T^2) \cos 2\phi, \quad (3)$$

where  $\hat{\mathbf{h}} \equiv \mathbf{q}_T/Q_T$ , with  $Q_T \equiv |\mathbf{q}_T|$ . This term, with its peculiar angular dependence, gives a parton model explanation for the  $\cos 2\phi$  asymmetry observed in the unpolarized  $\pi N$  Drell-Yan process [4].

From Eqs. (2) and (3) we get the following expression of the coefficient  $\nu$  in (1) (with  $\lambda = 1, \mu = 0$ ):

$$\nu = \frac{2\sum_{a} e_{a}^{2} \mathcal{H}[h_{1}^{\perp a}, h_{1}^{\perp a}]}{\sum_{a} e_{a}^{2} \mathcal{F}[f_{1}^{a}, f_{1}^{a}]},$$
(4)

where we used the notations:

$$\mathcal{F}[f_1^a, f_1^a] = \frac{1}{M^2} \int d^2 \mathbf{k}_T \, d^2 \mathbf{p}_T \delta^2 (\mathbf{k}_T + \mathbf{p}_T - \mathbf{q}_T) \\ \times f_1^a(x_1, \mathbf{k}_T^2) f_1^a(x_2, \mathbf{p}_T^2) \\ = \frac{1}{M^2} \int \mathrm{d}k_T \, k_T \, \int_0^{2\pi} \mathrm{d}\chi \\ \times f_1^a(x_1, \mathbf{k}_T^2) \, f_1^a(x_2, |\mathbf{q}_T - \mathbf{k}_T|^2) \,, \qquad (5)$$

$$\mathcal{H}[h_1^{\perp a}, h_1^{\perp a}] = \frac{1}{M^2} \int d^2 \mathbf{k}_T \, d^2 \mathbf{p}_T \delta^2 (\mathbf{k}_T + \mathbf{p}_T - \mathbf{q}_T) \\ \times \frac{(2\hat{\mathbf{h}} \cdot \mathbf{k}_T \hat{\mathbf{h}} \cdot \mathbf{p}_T - \mathbf{k}_T \cdot \mathbf{p}_T)}{M^2} \\ \times h_1^{\perp a}(x_1, \mathbf{k}_T^2) h_1^{\perp a}(x_2, \mathbf{p}_T^2) \\ = \frac{1}{M^2} \int \mathrm{d}k_T \, k_T \, \int_0^{2\pi} \mathrm{d}\chi \\ \times \frac{\mathbf{k}_T^2 + Q_T \, k_T \, \cos\chi - 2 \, \mathbf{k}_T^2 \, \cos^2\chi}{m_N^2} \\ \times h_1^{\perp a}(x_1, \mathbf{k}_T^2) \, h_1^{\perp a}(x_2, |\mathbf{q}_T - \mathbf{k}_T|^2) \,, \, (6)$$

and  $\chi$  is the angle between  $\mathbf{q}_T$  and  $\mathbf{k}_T$ . The asymmetry coefficient  $\nu$  given in Eq. (4) depends on the kinematic variables  $x_1, x_2, M$  and  $Q_T$ . The GSI-HESR kinematics probes the large x region, where the valence quarks and in particular the u sector dominate, so that Eq. (4) can be simplified to:

$$\nu = \frac{2\mathcal{H}[h_1^{\perp u}, h_1^{\perp u}]}{\mathcal{F}[f_1^{u}, f_1^{u}]}.$$
(7)

Another promising process to study transverse spin physics at GSI-HESR is  $J/\psi$  production, which has been

<sup>&</sup>lt;sup>1</sup> Concerning the perturbative contributions to azimuthal asymmetries, a forthcoming analysis of  $\cos 2\phi$  distributions in semiinclusive DIS shows that at moderate  $Q^2$  and low  $P_T$  the Boer–Mulders effect largely dominates over the perturbative contribution (at large  $Q^2$  the situation is reversed) [26].

proposed [27] as a method to access transversity by measuring double spin asymmetry. The  $J/\psi$  production events are identified by a peak in the dilepton invariant mass spectrum at  $M = m_{J/\psi} = 3.097$  GeV, so one can choose  $M^2 \simeq 9$  GeV<sup>2</sup>. At the GSI-HESR energy scale (s = 30-45GeV<sup>2</sup> in the fixed target mode, or s = 100 - 200 GeV<sup>2</sup> in the collider mode)  $J/\psi$  production is dominated by  $q\bar{q}$ annihilation [28]. Since the  $J/\psi$  is a vector particle and the  $q\bar{q}J/\psi$  coupling has the same helicity structure as the  $q\bar{q}\gamma^*$  coupling, one can get the  $J/\psi$  production cross section by replacing the quark electric charges by the  $J/\psi$ vector couplings to  $q\bar{q}$  and to  $\ell^+\ell^-$ ,

$$16\pi^2 \alpha_{\rm em}^2 e_a^2 \to (g_a^V)^2 (g_\ell^V)^2 \,,$$
 (8)

and the virtual photon propagator by a Breit–Wigner function,

$$\frac{1}{M^4} \to \frac{1}{(M^2 - m_{J/\psi}^2)^2 + m_{J/\psi}^2 \Gamma_{J/\psi}^2}, \qquad (9)$$

where  $\Gamma_{J/\psi}$  is the  $J/\psi$  width. This model successfully accounts for the SPS  $J/\psi$  production data at moderate s [29].

Therefore the unpolarized  $\cos 2\phi$  asymmetry in the  $J/\psi$  resonance region reads

$$\nu = \frac{2\sum_{a} (g_a^V)^2 \mathcal{H}[h_1^{\perp a}, h_1^{\perp a}]}{\sum_{a} (g_a^V)^2 \mathcal{F}[f_1^a, f_1^a]},$$
(10)

with only  $e_a^2$  replaced by  $(g_a^V)^2$  in Eq.(4). Since the *u* quark dominates, this asymmetry reduces to Eq. (7), which is the same as for continuum Drell-Yan, with  $M^2 \simeq 9$  GeV<sup>2</sup>. Integrating over  $x_1$  and  $x_2$  we get

$$\nu(Q_T, M) = \frac{2\int dx_1 \int dx_2 \mathcal{H}[h_1^{\perp u}, h_1^{\perp u}] \,\delta(1-\tau)}{\int dx_1 \int dx_2 \,\mathcal{F}[f_1^u, f_1^u] \,\delta(1-\tau)}, \quad (11)$$

where  $\tau = M^2/x_1x_2s$ . Notice that the relation  $1 - \tau = 0$  is valid for  $Q_T^2 \ll M^2$ . The rapidity is defined as  $y = \frac{1}{2} \ln(\frac{x_1}{x_2})$  and Feynman's variable is  $x_F = x_1 - x_2$ .

## **3** Calculation of the $\cos 2\phi$ asymmetry

To evaluate the  $\cos 2\phi$  asymmetry given in (7) one needs to know the form of the  $k_T$ -dependent distributions appearing in the transverse momentum convolution. Useful information on the Boer-Mulders function  $h_1^{\perp}(x, \mathbf{k}_T^2)$  can be obtained from the study of the  $\cos 2\phi$  azimuthal asymmetry in the unpolarized  $\pi N$  Drell-Yan processes, which has been measured by the NA10 Collaboration [4] and the E615 Collaboration [5]. In [10,11] this asymmetry was estimated by computing the  $h_1^{\perp}$  distribution of the pion and of the nucleon in a quark spectator model [12,30] and was compared with NA10 data. To compute the  $\cos 2\phi$ azimuthal asymmetry in the unpolarized  $p\bar{p}$  collision we adopt the same distributions  $h_1^{\perp}(x, \mathbf{k}_T)$  and  $f_1(x, \mathbf{k}_T)$  used in [11]. We assume that the observables are dominated by u quarks. The set of the transverse-momentum dependent distribution functions is (for simplicity, we consider a spectator scalar diquark [11,12])

$$f_1^u(x, \mathbf{k}_T^2) = N \left(1 - x\right)^3 \frac{(xm_N + m_q)^2 + \mathbf{k}_T^2}{(L^2 + \mathbf{k}_T^2)^4}, \quad (12)$$

$$h_1^{\perp u}(x, \mathbf{k}_T^2) = \frac{4\alpha_s}{3} N \left(1 - x\right)^3 \frac{m_N \left(xm_N + m_q\right)}{\left[L^2 \left(L^2 + \mathbf{k}_T^2\right)^3\right]}, (13)$$

where N is a normalization constant,  $m_q$  is the constituent quark mass, and

$$L^{2} = (1-x)\Lambda^{2} + x m_{d}^{2} - x (1-x) m_{N}^{2}.$$
 (14)

Here  $\Lambda$  is a cutoff appearing in the nucleon-quark-diquark vertex and  $m_d$  is the mass of the scalar diquark. As it is typical of all model calculations of quark distribution functions, we expect that Eqs.(12) and (13) should be valid at low  $Q^2$  values, of order of 1 GeV<sup>2</sup>. The average transverse momentum of quarks inside the nucleons, as computed from (12), turns out to be  $\langle k_T^2 \rangle^{1/2} \simeq 0.54$  GeV. For the parameters in Eqs.(12) and 13), we choose the values  $m_d = 0.8$  GeV,  $m_q = 0.3$  GeV,  $\Lambda = 0.6$  GeV,  $\alpha_s = 0.3$ , which are the same as in [11,14].

Compared with previous calculations of Drell-Yan asymmetries [9,18], our model differs for the explicit form of the proton-quark-diquark effective coupling and for the values of the parameters. We adopt a dipole form factor [12] for the effective coupling, whereas in other computations this coupling is taken as a constant [9], or as a Gaussian form factor [18]. This leads to different predictions on the magnitude and the  $Q_T$ -dependence of the cos  $2\phi$  asymmetry, as we will see below. Our model proved to be capable to reproduce the observed cos  $2\phi$  asymmetry of the NA10  $\pi^-N$  Drell-Yan data with the correct  $Q_T$ -dependence [11].

The Drell–Yan and  $J/\psi$  production events are reconstructed from the dilepton invariant mass spectrum, where the  $J/\psi$  events correspond to the peak at the invariant mass  $M = M_{J/\psi} \simeq 3$  GeV, and the genuine Drell–Yan events correspond to the continuum spectrum below and above the  $J/\psi$  peak. For the experimental programs at GSI-HESR, the center of mass energy is s = 30 - 45 GeV<sup>2</sup> in the fixed target mode and s = 100 - 200 GeV<sup>2</sup> for the collider option. With s = 45 GeV<sup>2</sup> and s = 200 GeV<sup>2</sup> one has on the  $J/\psi$  peak  $\tau = x_1x_2 = M^2/s \simeq 0.2$  and  $\tau \simeq 0.05$ , respectively. In these kinematic domains valence quarks dominate and the assumptions made above are justified.

The  $\cos 2\phi$  asymmetry  $\nu$  as a function of  $Q_T$  is shown in Fig. 1 for the fixed-target GSI kinematics. For a quantitative comparison, in the same figure we present the prediction of a model with constant quark-spectator coupling [9], obtained using the same parameters of [9] but for the kinematic domain we are considering here. We notice that both the magnitude and the  $Q_T$  dependence are quite different, similarly to what happens in the  $\pi N$  Drell-Yan process [11]. The shape of  $\nu$  in the model with a Gaussian quark-spectator coupling [18] also differs from ours and is similar to that of [9].

The  $Q_T$ -dependence of the  $\cos 2\phi$  asymmetry  $\nu$  in  $J/\psi$  production is shown in Fig. 2. As one can see, the asymmetry is sizable and increases with  $Q_T$ . Some difference

Fig. 1. The cos  $2\phi$  azimuthal asymmetry of Drell–Yan production in  $p\bar{p}$  collisions as a function of  $Q_T$ , for  $s = 45 \text{ GeV}^2$  and  $M^2 = 5 \text{ GeV}^2$ . The solid curve is our prediction. The dashed curve is the result of [9] extended to the kinematic region of interest here.

**Fig. 2.** The  $\cos 2\phi$  azimuthal asymmetry of  $p\bar{p} \to J/\psi X \to l^+ l^- X$  as a function of  $Q_T$ , for two values of *s* in the GSI-HESR kinematic domain.

between the two curves (corresponding to two values of s) emerges at large  $Q_T$ , where the asymmetry is suppressed for the larger center of mass energy. In Fig. 3 we plot  $\nu$ as a function of  $x_F = x_1 - x_2$ . The asymmetry lies in the range 0.2–0.3.

 $J/\psi$  production has been recently suggested by Anselmino et al. [27] as a candidate reaction to probe the nucleon transversity by measuring the double transverse spin asymmetry in polarized  $p^{\uparrow}\bar{p}^{\uparrow}$  process. The dilepton production rate on the  $J/\psi$  peak is two orders of magnitude larger than in the continuum region above the  $J/\psi$  mass. This makes  $J/\psi$  at GSI energies an excellent process to

 $\begin{array}{c} 0.4 \\ 0.3 \\ \hline \\ 0.2 \\ 0.1 \\ \hline \\ 0.0 \\ 0.0 \\ 0.0 \\ 0.2 \\ 0.2 \\ \hline \\ 0.0 \\ 0.0 \\ 0.2 \\ 0.4 \\ \hline \\ 0.4 \\ 0.6 \\ 0.4 \\ 0.6 \\ 0.8 \\ x_{\rm E} \end{array}$ 

Fig. 3. The  $\cos 2\phi$  azimuthal asymmetry of  $p\bar{p} \rightarrow J/\psi X \rightarrow l^+ l^- X$  as a function of  $x_F$ , for two values of s in the GSI-HESR kinematic domain.

measure transverse polarization asymmetries. Here we applied the same idea to the unpolarized case, and in particular to the  $\cos 2\phi$  asymmetry. Given the large value of  $\nu$  that we found, we can say that the experimental study of  $J/\psi$  and Drell-Yan production from unpolarized protonantiproton collisions at GSI represents a very important source of information on the Boer–Mulders distribution (of course, a complete analysis of these processes will also require a careful consideration of the perturbative effects).

#### 4 Conclusion

Vincenzo Barone et al.: The cos  $2\phi$  asymmetry of Drell-Yan and  $J/\psi$  production in unpolarized  $p\bar{p}$  scattering

In summary, we calculated the  $\cos 2\phi$  azimuthal asymmetry of the unpolarized  $p\bar{p}$  dilepton production in the continuum region and on the  $J/\psi$  peak for the GSI kinematics, relying on a model of the Boer-Mulders function previously adjusted to fit the available experimental data on  $\pi N$  Drell-Yan. The asymmetry turns out to be rather large, of order 0.2–0.3. The size of the asymmetry and the high counting rate in the  $J/\psi$  resonance region make the dilepton production in  $p\bar{p}$  scattering at moderate energies a very promising process to detect the Boer-Mulders function in the early unpolarized stages of the future GSI experiments.
