

BIHOLOMORPHIC MAPPING ON THE BOUNDARY I

Won K. Park Department of Mathematics, University of Seoul wonkpark@hotmail.com

ABSTRACT. We present a new proof of Chern-Ji's mapping theorem on a strongly pseudoconvex domain with differentiable spherical boundary. We show that a proper holomorphic self mapping of a strongly pseudoconvex domain with the real analytic boundary is biholomorphic.

0. INTRODUCTION AND PRELIMINARIES

We shall show that a bounded domain D is biholomorphic to an open ball B^{n+1} whenever the boundary bD is locally biholomorphic to the boundary of an open ball B^{n+1} .

Theorem 1. *Let D be a simply connected bounded domain in \mathbb{C}^{n+1} with differentiable spherical boundary bD . Suppose that there is a biholomorphic mapping*

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D})$$

for a connected open neighborhood U of a point $p \in bD$ satisfying

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Then the mapping ϕ is analytically continued to a biholomorphic mapping from D onto B^{n+1} .

Our result is a new proof of a weaker version of Chern-Ji's mapping theorem [CJ]. The main steps of our proof come as follows: We show that the inverse mapping ϕ^{-1} is analytically continued on the unit ball B^{n+1} to be a locally biholomorphic mapping

$$\varphi : B^{n+1} \rightarrow D.$$

We show that the mapping φ is a proper holomorphic mapping onto a universal covering Riemann domain over D . Thus the mapping φ is a biholomorphic mapping whenever D is simply connected.

We shall study on a proper holomorphic mapping ϕ between strongly pseudoconvex bounded domains D, D' with real analytic boundaries bD, bD' .

Theorem 2. *Let D, D' be strongly pseudoconvex bounded domains in \mathbb{C}^{n+1} with real analytic boundaries bD, bD' and $\phi : D \rightarrow D'$ be a proper holomorphic mapping. Then the mapping ϕ is locally biholomorphic. If $D = D'$, then the mapping ϕ is a biholomorphic self mapping.*

Our result is a new proof of a weaker version of Pinchuk's mapping theorem [Pi]. The main steps of our proof come as follows: We show that the mapping ϕ is analytically continued along any path on bD as a locally biholomorphic mapping when bD is nonspherical so that the mapping $\phi : D \rightarrow D'$ are locally biholomorphic. From the study of Theorem 1, we show that the same is true when bD is spherical so that the mapping $\phi : D \rightarrow D'$ are locally biholomorphic. For the case of $D = D'$, we show that the boundary bD is necessarily spherical whenever the claim is not

true. Then we show that there is a sequence of automorphisms $\phi_j \in \text{Aut}(D)$ and a sequence of points p_j on a compact subset $K \subset\subset D$ such that

$$\phi_j(p_j) \rightarrow bD$$

whenever the boundary bD is spherical and the claim is not true. We apply Wong-Rosay Theorem so that the domain D is biholomorphic to an open ball B^{n+1} . Then we obtain a contradiction that the mapping ϕ induces a nonautomorphic proper self mapping of an open ball B^{n+1} whenever the boundary bD is spherical and the claim is not true.

We remark that Theorem 1 is a weaker version of the following theorem:

Theorem 3 (cf. Chern-Ji [CJ]). *Let D be a simply connected bounded domain in \mathbb{C}^{n+1} with continuous spherical boundary bD . Suppose that there is a biholomorphic mapping*

$$\phi \in H(U \cap D) \cap C(U \cap \overline{D})$$

for a connected open neighborhood U of a point $p \in bD$ satisfying

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Then the mapping ϕ is analytically continued to a biholomorphic mapping from D onto B^{n+1} .

We remark that Theorem 2 is a weaker version of the following theorem:

Theorem 4 (cf. Pinchuk [Pi]). *Let D, D' be strongly pseudoconvex bounded domains in \mathbb{C}^{n+1} with the boundaries bD, bD' of class C^2 and $\phi : D \rightarrow D'$ be a proper holomorphic mapping. Then the mapping ϕ is locally biholomorphic. If $D = D'$, then the mapping ϕ is a biholomorphic self mapping.*

We presented parts of this article in the spring meeting of Korean Mathematical Society in 2000. This article is a preliminary version. Any comment shall be greatly appreciated. Send your comments to wonkpark@hotmail.com.

0.1. Canonical normalizing mapping. Let M be a nondegenerate analytic real hypersurface in \mathbb{C}^{n+1} . For each point $p \in M$, there is a complex tangent hyperplane $H_p \subset T_p M$ so that there is a unit tangent vector $v_p \in T_p M$ perpendicular to the complex tangent hyperplane H_p with respect to the usual riemannian metric in $\mathbb{C}^{n+1} = \mathbb{R}^{2n+2}$. Then we can take a unique distinguished chain γ_p tangential to the direction v_p and passing through the complex tangent hyperplane H_p at the point p on M (cf. [Pa3]). Further, there is a distinguished normal parametrization on the chain γ_p having the same values up to order 2 of the straight real line to the direction v_p with the usual euclidean parametrization.. Therefore, we can take a distinguished normalizing mapping μ_p to Moser normal form

$$\mu_p : M \rightarrow \mu_p(M)$$

sending the germ M at the point p to a normal form such that $\mu_p(p)$ is the origin and $\mu_p(\gamma_p)$ is on the straightened chain of the normal form.

We take a local orientation near the point $p \in M$ so that the tangent vector v_p extends to a smooth unit vector field v on $M \cap U$ for an open neighborhood U of the point p such that $v_q \in T_q M$ is a unit tangent vector perpendicular to the

complex tangent hyperplane H_q for each $q \in M \cap U$. Then we obtain a family of the distinguished normalizing mapping μ_q for $q \in M \cap U$:

$$\mu_q : M \rightarrow \mu_q(M)$$

associated the unit tangent vector $v_q \in T_q M \setminus H_q$. The distinguished normalizing mapping μ_q shall be called the canonical normalizing mapping associated Moser normal form.

Lemma 5. *Let $p_j \in M$ be a sequence of points converging to a point $p \in M$. Then there is a positive real number $\delta > 0$ such that*

1. *the mapping μ_{p_j} and its inverse $\mu_{p_j}^{-1}$ are analytically continued respectively on*

$$B(p_j; \delta) \quad \text{and} \quad B(0; \delta)$$

as a biholomorphic mapping,

2. *the real hypersurface $\mu_{p_j}(M)$ is analytically continued on $B(0; \delta)$ by its defining equation,*
3. *the sequence $\mu_{p_j}^{-1}$ uniformly converges to μ_p^{-1} on $B(0; \delta)$ as a biholomorphic mapping,*
4. *the sequence $\mu_{p_j}(M)$ uniformly converges on $B(0; \delta)$ to the real hypersurface $\mu_p(M)$.*

Let H be the local automorphism group at the origin of the real hyperquadric

$$v = \langle z, z \rangle.$$

The isotropy subgroup $Aut_p(M)$ is naturally identified to the isotropy subgroup $Aut_0(\mu_p(M))$ by the following relation:

$$\mu_p \circ \phi \circ \mu_p^{-1} \in Aut_0(\mu_p(M)) \quad \text{for} \quad \phi \in Aut_p(M).$$

Note that every biholomorphic mapping φ between real hypersurfaces in normal form is faithfully represented by a natural group action of the isotropy subgroup H (cf. [Pa3]) such that

$$\varphi = N_e \quad \text{for} \quad e \in H.$$

Because $\mu_p(M)$ is in normal form, there is a natural identification of a local automorphism $\phi \in Aut_p(M)$ to an element

$$(U_\phi, a_\phi, \rho_\phi, r_\phi) \in H,$$

where $U_\phi, a_\phi, \rho_\phi, r_\phi$ are the normalizing parameters(cf. [Pa3]) of the mapping

$$\mu_p \circ \phi \circ \mu_p^{-1} \in Aut_0(\mu_p(M)).$$

Lemma 6. *If the isotropy subgroup $Aut_p(M)$ is compact, then $Aut_p(M)$ is isomorphic to the subgroup*

$$\{(U_\phi, a_\phi, \rho_\phi, r_\phi) \in H : \phi \in Aut_p(M)\}$$

as a Lie group.

0.2. Preliminary Lemmas. We have lemmas on the automorphism of B^{n+1} .

Lemma 7. *Let p, q be two distinct points on bB^{n+1} and $\phi \in \text{Aut}(bB^{n+1})$ be a local automorphism of bB^{n+1} such that*

$$\phi(p) \neq q.$$

Then there is a unique decomposition

$$\phi = \psi \circ \varphi$$

where

$$\varphi \in \text{Aut}_p(bB^{n+1}), \quad \psi \in \text{Aut}_q(bB^{n+1})$$

and the local automorphism ψ acts trivially on the complex tangent hyperplane of bB^{n+1} at the fixed point q .

Proof. Note that the isotropy subgroup $\text{Aut}_q(bB^{n+1})$ acts on $bB^{n+1} \setminus q$ transitively. Further, there is a unique element $\psi \in \text{Aut}_q(bB^{n+1})$ for each point displacement on $bB^{n+1} \setminus q$ by requiring the element ψ acts trivially on the complex tangent hyperplane of bB^{n+1} at the point q (cf. [Pa1]).

Let's put $p' = \phi(p)$. Since $p' \neq q$, we take a unique automorphism $\psi \in \text{Aut}_q(bB^{n+1})$ such that

$$\psi(p') = p.$$

Then $\varphi \equiv \psi \circ \phi \in \text{Aut}_p(bB^{n+1})$ so that

$$\phi = \psi^{-1} \circ \varphi.$$

This completes the proof. □

Lemma 8. *Let p, q be two distinct points on bB^{n+1} and $\phi \in \text{Aut}(bB^{n+1})$ be a local automorphism of bB^{n+1} such that*

$$p' \equiv \phi(p) \neq q.$$

Then there is a unique decomposition

$$\phi = \varphi \circ \psi$$

where

$$\varphi \in \text{Aut}_{p'}(bB^{n+1}), \quad \psi \in \text{Aut}_q(bB^{n+1})$$

and the local automorphism ψ acts trivially on the complex tangent hyperplane of bB^{n+1} at the fixed point q .

Proof. By Lemma 8, there is a decomposition

$$\phi^{-1} = \psi \circ \varphi$$

where

$$\varphi \in \text{Aut}_{p'}(bB^{n+1}), \quad \psi \in \text{Aut}_q(bB^{n+1})$$

and the local automorphism ψ acts trivially on the complex tangent hyperplane of bB^{n+1} at the fixed point q . Hence we obtain

$$\phi = \varphi^{-1} \circ \psi^{-1}$$

where

$$\varphi^{-1} \in \text{Aut}_{p'}(bB^{n+1}), \quad \psi^{-1} \in \text{Aut}_q(bB^{n+1}).$$

This completes the proof. \square

Lemma 9. *Let ϕ_j be a sequence of automorphisms of B^{n+1} . Suppose that the sequence ϕ_j converges to a holomorphic mapping λ uniformly on every compact subset of B^{n+1} . Then the mapping λ is either a constant mapping or an automorphism of B^{n+1} .*

Proof. Note that the mapping λ satisfies

$$(1) \quad \lambda(B^{n+1}) \subset \overline{B^{n+1}}$$

and a complex line is mapped to a complex line under the biholomorphic automorphism of the unit ball B^{n+1} .

Suppose that there is a complex line π such that

$$\pi \cap B^{n+1} \neq \emptyset \quad \text{and} \quad \lambda(\pi \cap B^{n+1}) = \emptyset.$$

Note that bB^{n+1} is strongly pseudoconvex so that, by the condition 1, there is a point $q \in bB^{n+1}$ satisfying

$$q = \lambda(\pi) \cap \overline{B^{n+1}}.$$

Then we obtain

$$\lambda|_{\pi \cap B^{n+1}} = q.$$

Let x be an interior point of $\pi \cap B^{n+1}$ and p' be an arbitrary point of B^{n+1} so that we take a complex line π' passes through x and p' . Since B^{n+1} is strongly pseudoconvex, the maximum modulus theorem of one complex variable yields

$$\lambda|_{\pi' \cap B^{n+1}} = q$$

so that the mapping λ is a constant mapping.

Suppose that the mapping λ is not a constant mapping. Then, for a complex line π satisfying

$$\pi \cap B^{n+1} \neq \emptyset,$$

there is a real number $\varepsilon > 0$ such that

$$(2) \quad |\phi_j(\pi \cap B^{n+1})| \geq \varepsilon$$

where $|\phi_j(\pi \cap B^{n+1})|$ is the area of the analytic disk

$$\phi_j(\pi \cap B^{n+1}).$$

We take a point $p \in \pi \cap bB^{n+1}$ so that

$$(3) \quad \phi_j(p) \rightarrow p' \in bB^{n+1}.$$

Then we take a point $p'' \in bB^{n+1}$ such that

$$p'' \notin \overline{\{\phi_j(p) : j \in \mathbb{N}^+\}},$$

if necessary, passing to a subsequence. We have the following decomposition

$$\phi_j = \varphi_j \circ \psi_j$$

where

$$\varphi_j \in \text{Aut}_{p'}(bB^{n+1}) \quad \text{and} \quad \psi_j \in \text{Aut}_{p''}(bB^{n+1})$$

where the automorphisms ψ_j act trivially on the complex tangent hyperplane at the fixed point p'' . Then we obtain

$$U_{\psi_j} = id_{n \times n}, \quad \rho_{\psi_j} = 1.$$

By the condition 3, there is a real number $e > 0$ such that

$$|a_{\psi_j}| \leq e, \quad |r_{\psi_j}| \leq e.$$

By the condition 2, there is a real number $e > 0$, if necessary, increasing e , such that

$$|a_{\varphi_j}| \leq e.$$

Since the mapping λ is not a constant mapping, there is a real number $e > 0$, if necessary, increasing e , such that

$$e^{-1} \leq |\rho_{\varphi_j}| \leq e, \quad |r_{\varphi_j}| \leq e.$$

Since bB^{n+1} is strongly pseudoconvex, we have

$$|U_{\varphi_j}| = 1.$$

Then the Jacobian determinant $\det \varphi'_j$ is uniformly bounded from the zero on an open neighborhood of the point $p \in bB^{n+1}$. By Hurwitz theorem, the mapping λ is locally biholomorphic and, further, the mapping λ is one-to-one. Hence the mapping λ is an automorphism of the unit ball B^{n+1} . This completes the proof. \square

We have lemmas on the chain of bB^{n+1} .

Lemma 10. *Let $\gamma : [0, 1] \rightarrow bB^{n+1}$ be a chain-segment on bB^{n+1} . Then there is a complex line π such that*

$$\gamma[0, 1] \subset \pi \cap bB^{n+1}.$$

Proof. We take a point $p \in \gamma[0, 1]$. Then the chain-segment $\mu_p \circ \gamma[0, 1]$ on $\mu_p(bB^{n+1})$ is on a complex line π' (cf. [Pa3]). Since the canonical normalizing mapping μ_p of the sphere bB^{n+1} is a fractional linear mapping (cf. [Pa3]), we take

$$\pi = \mu_p^{-1}(\pi')$$

so that

$$\gamma[0, 1] \subset \pi \cap bB^{n+1}.$$

This completes the proof. \square

Lemma 11. *Let π be a complex line such that*

$$\pi \cap B^{n+1} \neq \emptyset.$$

Then the circle $\pi \cap bB^{n+1}$ is a chain on bB^{n+1} .

Proof. We take a point $p \in \pi \cap bB^{n+1}$. Then we obtain

$$\mu_p(\pi) \cap \mu_p(bB^{n+1}) = \mu_p(\pi \cap bB^{n+1}) \neq \emptyset.$$

Since the canonical normalizing mapping μ_p of the sphere bB^{n+1} is a fractional linear mapping(cf. [Pa3]), $\mu_p(\pi)$ is a complex line so that $\mu_p(\pi) \cap \mu_p(bB^{n+1})$ is a chain(cf. [Pa3]). Thus the circle

$$\pi \cap bB^{n+1} = \mu_p^{-1}(\mu_p(\pi) \cap \mu_p(bB^{n+1}))$$

is a chain as well. This completes the proof. \square

Lemma 12. *Let γ be a chain passing through a point $p \in bB^{n+1}$ and δ_γ be an analytic disk such that*

$$\gamma = \pi \cap bB^{n+1} \quad \text{and} \quad \delta_\gamma = \pi \cap B^{n+1}$$

where π is a complex line. Let θ_γ be the angle between the tangent vector of γ at the point p and a unit vector v_p perpendicular to the complex tangent hyperplane at the point $p \in bB^{n+1}$ and $|\delta_\gamma|$ be the area of the analytic disk δ_γ . Then

$$|a_\gamma| \equiv |\tan \theta_\gamma| \rightarrow \infty$$

if and only if

$$|\delta_\gamma| \rightarrow 0.$$

Proof. We easily see that

$$\theta_\gamma \rightarrow \frac{\pi}{2}$$

if and only if

$$|a_\gamma| \equiv |\tan \theta_\gamma| \rightarrow \infty.$$

Note that the complex line π would be on the complex tangent hyperplane of bB^{n+1} at the point p if

$$\theta_\gamma = \frac{\pi}{2}.$$

Since bB^{n+1} is strongly pseudoconvex and B^{n+1} is strongly convex, the complex tangent hyperplane of bB^{n+1} at the point p has no intersection to B^{n+1} . Thus we easily see

$$\theta_\gamma \rightarrow \frac{\pi}{2}$$

if and only if

$$|\delta_\gamma| \rightarrow 0.$$

This completes the proof. \square

We may require the following well-known results in this article(cf. [Kr], [Ra], [Bo]).

Lemma 13 (Lewy, Pinchuk). *Let D, D' be domains with strongly pseudoconvex real analytic boundaries bD, bD' and U be a connected open neighborhood of a point $p \in bD$. Suppose that there is a holomorphic mapping ϕ on $U \cap D$ such that*

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D}), \quad \phi(U \cap bD) \subset bD'$$

and the induced mapping $\phi : U \cap bD \rightarrow bD'$ is CR diffeomorphic. Then the mapping ϕ is analytically continued on U , if necessary, shrinking U .

Lemma 14 (Lewy). *Let D be a domain with a strongly pseudoconvex boundary bD and U be an open connected neighborhood of a point $p \in bD$. Suppose that there is a holomorphic mapping ϕ on $U \cap bD$. Then there is an open neighborhood V of the point p such that the mapping ϕ is analytically continued onto*

$$V \cap \overline{D}.$$

Lemma 15 (Wong, Rosay). *Let D be a strongly pseudoconvex bounded domain. Suppose that there is a compact set $K \subset\subset D$ and a sequence $p_j \in K$ and automorphisms $\phi_j \in \text{Aut}(D)$ such that*

$$\phi_j(p_j) \rightarrow bD.$$

Then the domain D is biholomorphic to an open unit ball B^{n+1} .

Lemma 16 (Bell-Catlin, Diederich-Fornaess). *Let D, D' be strongly pseudoconvex bounded domains with the boundaries bD, bD' of class C^∞ and $\phi : D \rightarrow D'$ be a proper holomorphic mapping. Then $\phi : D \rightarrow D'$ is a locally biholomorphic mapping and the induced mapping $\phi : bD \rightarrow bD'$ is a locally CR diffeomorphism.*

1. ANALYTIC CONTINUATION ON A SPHERE

1.1. Analytic continuation with finiteness. Let D be a domain in \mathbb{C}^{n+1} , $n \geq 1$, with real analytic boundary bD . The boundary bD shall be called spherical if, for each point $p \in bD$, there is a connected open neighborhood U of the point p and a biholomorphic mapping ϕ on U such that

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Note that a domain D with spherical real analytic boundary is necessarily strongly pseudoconvex.

Lemma 17. *Let p be a point of bB^{n+1} and U be a connected open neighborhood of the point p . Suppose that there is a biholomorphic mapping ϕ on U such that*

$$(4) \quad \phi(U \cap bB^{n+1}) \subset bB^{n+1}.$$

Then the mapping ϕ is analytically continued on an open neighborhood of the closed ball $\overline{B^{n+1}}$.

Proof. Note that each local automorphism $\varphi \in \text{Aut}_p(bB^{n+1})$ for any point $p \in bB^{n+1}$ is necessarily birational such that φ is analytically continued on an open neighborhood of $\overline{B^{n+1}}$ as a biholomorphic mapping(cf.[Pa1]).

Let's put $q = \phi(p)$. We take a point $r \in bB^{n+1}$ such that $r \neq p$, $r \neq q$. Then we take an automorphism

$$\psi \in \text{Aut}_r(bB^{n+1})$$

satisfying

$$\psi(q) = p$$

so that

$$\varphi \equiv \psi \circ \phi \in \text{Aut}_p(bB^{n+1}).$$

Then the mapping $\psi^{-1} \circ \phi$ is an automorphism of B^{n+1} and an analytic continuation of the mapping ϕ such that

$$\phi = \psi^{-1} \circ \phi \quad \text{on } U.$$

This completes the proof. \square

Theorem 18. *Let D be a domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD . Suppose that there is a connected open neighborhood U of a point $p \in bD$ and a biholomorphic mapping ϕ on U such that $\phi(U \cap bD) \subset bB^{n+1}$. Then the mapping ϕ is analytically continued along any path on bD as a local biholomorphic mapping.*

Proof. Suppose that the assertion is not true. Then there would be a path $\gamma : [0, 1] \rightarrow bD$ such that $\gamma(0) \in U \cap bD$ and the germ of a biholomorphic mapping ϕ at the point $\gamma(0)$ is analytically continued along the subpath $\gamma[0, \tau]$ with all $\tau < 1$ as a local biholomorphic mapping, but not the whole path $\gamma[0, 1]$.

Since bD is spherical, by definition, there exist a connected open neighborhood V of the point $\gamma(1)$ and a biholomorphic mapping φ on V such that

$$\varphi(V \cap bD) \subset bB^{n+1}.$$

We take $\lambda \in [0, 1)$ such that

$$\gamma(\tau) \in V \cap bD \quad \text{for all } \tau \in [\lambda, 1]$$

and we take a sufficiently small connected open neighborhood W of the point $\gamma(\lambda)$ such that ϕ is analytically continued on $W \subset V$ along the path $\gamma[0, \lambda]$ and

$$\varphi(W) \cap bB^{n+1} \neq \emptyset.$$

Then we have

$$\psi(\varphi(W) \cap bB^{n+1}) \subset bB^{n+1}$$

where

$$\psi = \phi \circ \varphi^{-1}.$$

By Lemma 17, ψ is analytically continued on an open neighborhood of bB^{n+1} as a local biholomorphic mapping. By abuse of notation, the mapping $\psi \circ \varphi$ is biholomorphic on the open set V such that

$$\psi \circ \varphi = \phi \quad \text{on } W.$$

Thus the germ $\psi \circ \varphi$ at the point $\gamma(1)$ is an analytic continuation of the germ ϕ at the point $\gamma(0)$ along the path $\gamma[0, 1]$ as a local biholomorphic mapping. This contradiction completes the proof. \square

Lemma 19. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD such that the fundamental group $\pi_1(bD)$ is finite. Suppose that there is a connected open neighborhood U of a point $p \in bD$ and a biholomorphic mapping ϕ on U such that $\phi(U \cap bD) \subset bB^{n+1}$. Then ϕ is analytically continued to a biholomorphic mapping from D onto B^{n+1} .*

Proof. By Lemma 18, the mapping ϕ is analytically continued along any path on bD as a local biholomorphic mapping. Let E be the path space of bD pointed at the point p mod homotopy so that E is a universal covering of bD with a natural CR structure and a CR projection $\varphi : E \rightarrow bD$. Then there is a unique CR lift $\psi : E \rightarrow bB^{n+1}$ as the analytic continuation of the biholomorphic mapping ϕ . Note

that $\psi : E \rightarrow bB^{n+1}$ is an open mapping because ϕ and φ are both locally CR diffeomorphisms.

Since bD is finitely connected, E is necessarily compact so that the mapping $\psi : E \rightarrow bB^{n+1}$ is surjective. Further, the mapping $\psi : E \rightarrow bB^{n+1}$ is a simple covering map because ψ is locally a CR diffeomorphism and the sphere bB^{n+1} is simply connected. Hence there exists a locally biholomorphic mapping $\lambda : bB^{n+1} \rightarrow bD$ defined by

$$\lambda = \varphi \circ \psi^{-1} \quad \text{on} \quad bB^{n+1}.$$

By Hartogs extension theorem, the mapping λ uniquely extends to the open ball B^{n+1} as a local biholomorphic mapping and, further, the extension is smooth up to the boundary. Hence λ is well defined as a locally biholomorphic mapping on an open neighborhood of $\overline{B^{n+1}}$ by Lemma 13.

We obtain a proper mapping $\lambda : B^{n+1} \rightarrow D$ so that λ is a globally branched covering and the branched locus of λ cannot be bounded by bD . Since $\lambda^{-1} = \phi$ is locally biholomorphic on bD , $\lambda : B^{n+1} \rightarrow D$ and $\lambda : bB^{n+1} \rightarrow bD$ are finite coverings respectively of D and bD . Since the closed ball $\overline{B^{n+1}}$ has the fixed point property, the mapping $\lambda : B^{n+1} \rightarrow D$ is globally one-to-one. Otherwise, there would be a nontrivial deck transform of $\overline{B^{n+1}}$ which is continuous on $\overline{B^{n+1}}$ without a fixed point. Hence the mapping $\lambda^{-1} : D \rightarrow B^{n+1}$ is biholomorphic with $\lambda^{-1} = \phi$ on bD . This completes the proof. \square

Theorem 20. *Let D be a bounded domain in \mathbb{C}^{n+1} with a connected spherical real analytic boundary bD . Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ satisfying*

$$\phi(U \cap bD) \subset bB^{n+1}$$

such that the analytic continuation of ϕ on the boundary bD yields finitely many germs at each point on bD . Then D is necessarily simply connected and the mapping ϕ is analytically continued to a biholomorphic mapping from D onto B^{n+1} .

Proof. We claim that there is a finite covering space E_1 of bD with a natural CR structure and a CR projection $\varphi_1 : E_1 \rightarrow bD$ and a local CR diffeomorphism $\psi_1 : E_1 \rightarrow bB^{n+1}$ satisfying the relation $\psi_1 = \phi \circ \varphi_1$. Then the desired result follows from this claim by the same argument in the proof of Lemma 19.

Let E be the path space of bD pointed at the point $p \in bD$ mod homotopy so that E is a universal covering of bD with a natural CR structure and a CR projection $\varphi : E \rightarrow bD$. Then there is a unique CR lift $\psi : E \rightarrow bB^{n+1}$:

$$\begin{array}{ccc} E & & \\ \downarrow \varphi & \searrow \psi & \\ bD & \xrightarrow{\phi} & bB^{n+1} \end{array}$$

satisfying the relation $\psi = \phi \circ \varphi$. Note that $\psi : E \rightarrow bB^{n+1}$ is an open mapping because ϕ and φ are both local CR diffeomorphisms. Let F be the image of the mapping ψ such that $F = \psi(E)$. Then F is an open subset of bD .

Suppose that $bF \neq \emptyset$. Then we take a point $p \in bF$ and a sequence $p_j \in F$ such that $p_j \rightarrow p$. Thus there exists a point $q_j \in bD$ and germs of biholomorphic mappings ϕ_j such that

$$\phi_j(q_j) \rightarrow p$$

where ϕ_j are analytic continuations of the mapping ϕ on bD . Since bD is compact, there exist a point $q \in bD$ and a subsequence q_{m_j} of q_j such that $q_{m_j} \rightarrow q$. Further, by passing to a subsequence, if necessary, we may assume that

$$\phi^* = \phi_{m_j} \quad \text{for all } m_j$$

because the analytic continuation of the mapping ϕ yields only finitely many germs at the point $q \in bD$. Hence we obtain

$$\phi^*(q) = \lim_{j \rightarrow \infty} \phi_{m_j}(q_{m_j}) = p \in F.$$

This contradiction implies that $bF = \emptyset$, i.e., $\psi(E) = bB^{n+1}$.

For each point $q \in bB^{n+1}$, there is a subset $X_q \subset E$ such that

$$X_q = \{p \in E : \psi(p) = q\}.$$

Since ψ is a CR diffeomorphism, X_q is necessarily a discrete set on E . Then we define a subset $Y_q \subset bD$ such that

$$Y_q = \{\varphi(p) \in bD : p \in X_q\}.$$

Suppose that Y_q has an accumulation point $y \in bD$. Then there is a sequence of point $p_j \in bD$ satisfying

$$p_j \rightarrow y \quad \text{and} \quad p_j \neq y,$$

and biholomorphic mappings ϕ_j such that

$$\phi_j(p_j) = q$$

where the mapping ϕ at the point p_j is the analytic continuation of the mapping ϕ . Because the analytic continuation of ϕ yields only finitely many germs at the point y , we can take a subsequence of ϕ and a biholomorphic mapping ϕ^* such that $\phi^* = \phi_{m_j}$. Then we have

$$\phi^*(y) = \lim_{j \rightarrow \infty} \phi_{m_j}(p_{m_j}) = q.$$

Since ϕ^* is locally biholomorphic, it is impossible that $\phi^*(p_{m_j}) = q = \phi^*(y)$ and $p_{m_j} \rightarrow y, p_{m_j} \neq y$ at the same time. Thus we find that the set Y_q is finite.

Therefore, the analytic continuation of the mapping ϕ on bD is mapped to a point of bB^{n+1} only at finitely many points of bD . Since the analytic continuation of the mapping ϕ yields finitely many germs at each point on bD , only finitely many germs of the analytic continuation of the mapping ϕ on bD are mapped to each point of bB^{n+1} . Then, by the compactness of bB^{n+1} , we obtain a finite covering space E_1 of bD satisfying all conditions in the claim. This completes the proof. \square

1.2. First Dogginal Lemma.

Lemma 21 (First Scaling Lemma). *Let p be a point of the boundary bB^{n+1} and $p_j, j \in \mathbb{N}^+$, be a sequence of points of bB^{n+1} such that $p_j \neq p$ for all j and $p_j \rightarrow p$ as $j \rightarrow \infty$ to a direction transversal to the complex tangent hyperplane at the point $p \in bB^{n+1}$. Let ε_j be the euclidean distance between the two points p_j and p , and δ_j be the analytic disk*

$$\delta_j = \pi_j \cap B^{n+1}$$

where π_j is the complex line passing through the two points p_j and p . Suppose that there is a sequence p'_j of points of bB^{n+1} satisfying

$$p'_j \rightarrow p' \in bB^{n+1},$$

and a sequence of biholomorphic automorphisms $\phi_j \in \text{Aut}(B^{n+1})$ satisfying

$$\phi_j(p'_j) = p_j$$

such that the sequence ϕ_j converges to a constant mapping and the area $|\phi_j^{-1}(\delta_j)|$ of the analytic disks

$$\phi_j^{-1}(\delta_j)$$

is bounded from the below, i.e., there is a real number $c > 0$ satisfying

$$|\phi_j^{-1}(\delta_j)| \geq c.$$

Then there is a subsequence ϕ_{m_j} and a sequence of local automorphisms $\sigma_j \in \text{Aut}_{p_{m_j}}(B^{n+1})$ such that

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_{m_j}, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0$$

and the composition

$$\sigma_j^{-1} \circ \phi_{m_j} : B^{n+1} \rightarrow B^{n+1}$$

uniformly converges to an automorphism of the unit ball B^{n+1} .

Proof. Note that there is a subsequence ϕ_{m_j} which converges to the point $p \in bB^{n+1}$ uniformly on every compact subset of the unit ball B^{n+1} . We take a point $p' \in bB^{n+1}$ such that $p' \neq p$ and

$$p' \notin \overline{\{p_{m_j} : j \in \mathbb{N}^+\}},$$

if necessary, passing to a subsequence.. Then, by Lemma 8, there is a unique decomposition of the automorphism ϕ_{m_j} such that

$$\phi_{m_j} = \varphi_j \circ \psi_j$$

where

$$\varphi_j \in \text{Aut}_{p_{m_j}}(bB^{n+1}), \quad \psi_j \in \text{Aut}_{p'}(bB^{n+1})$$

and the local automorphism ψ_j acts trivially on the complex tangent hyperplane of bB^{n+1} at the fixed point p' .

Let $U_{\psi_j}, \rho_{\psi_j}, a_{\psi_j}, r_{\psi_j}$ be the normalizing parameters of the local automorphism ψ_j . Since the local automorphism ψ_j acts trivially on the complex tangent hyperplane of bB^{n+1} at the fixed point p' , we obtain

$$U_{\psi_j} = id_{n \times n}, \quad \rho_{\psi_j} = 1.$$

Since the sequence ϕ_{m_j} uniformly converges to the point p , there is a real number $e > 0$ such that

$$(5) \quad |a_{\psi_j}| \leq e, \quad |r_{\psi_j}| \leq e.$$

Let π_j be the complex line passing through the two points p and p_{m_j} . Since the points p_j converges to the point p to a direction transversal to the complex tangent hyperplane at the point $p \in bB^{n+1}$, the analytic disks

$$\delta_j = \pi_j \cap B^{n+1}$$

is uniformly bounded in their area from the below by a positive number.

Let $U_{\varphi_j}, \rho_{\varphi_j}, a_{\varphi_j}, r_{\varphi_j}$ be the normalizing parameters of the local automorphism φ_j . Note that the analytic disk

$$\phi_{m_j}^{-1}(\delta_j)$$

is mapped by ϕ_{m_j} onto the analytic disk δ_j , where the areas of the analytic disks in both classes

$$\left| \phi_{m_j}^{-1}(\delta_j) \right| \quad \text{and} \quad |\delta_j|$$

are bounded from the below. Since the chain $\phi_{m_j}^{-1}(b\delta_j)$ is mapped by ϕ_{m_j} to the chain $b\delta_j$, there is a real number $e > 0$, if necessary, increasing e , such that

$$(6) \quad |a_{\varphi_j}| \leq e.$$

Since the area of the analytic disks δ_j is bounded by a positive number, the point p is attracted to the center of the local automorphism $Aut_{p_{m_j}}(bB^{n+1})$. Then, by passing to a subsequence, if necessary and increasing e , there is a real number $e > 0$ such that

$$(7) \quad |r_{\varphi_j}| \leq e$$

and

$$\rho_{\varphi_j} \rightarrow 0 \quad \text{as } j \rightarrow \infty.$$

Since bB^{n+1} is strongly pseudoconvex, we obtain

$$|U_{\varphi_j}| = 1.$$

Let η_j be a local automorphism in $Aut_{p_{m_j}}(bB^{n+1})$ defined by the normalizing parameters

$$U_{\eta_j} = id_{n \times n}, \quad \rho_{\eta_j} = \rho_{\varphi_j}, \quad a_{\eta_j} = 0, \quad r_{\eta_j} = 0.$$

Then the composition

$$\varphi'_j \equiv \eta_j^{-1} \circ \varphi_j \in Aut_{p_{m_j}}(bB^{n+1})$$

has the same normalizing parameters of the mapping φ_j except for $\rho_{\varphi'_j} = 1$, i.e.,

$$U_{\varphi'_j} = U_{\varphi_j}, \quad \rho_{\varphi'_j} = 1, \quad a_{\varphi'_j} = a_{\varphi_j}, \quad r_{\varphi'_j} = r_{\varphi_j}.$$

Therefore, by passing to a subsequence, if necessary, the sequence

$$\tau_j \equiv \eta_j^{-1} \circ \phi_{m_j} : B^{n+1} \rightarrow B^{n+1}$$

converges by Hurwitz theorem to a locally biholomorphic mapping. Since τ_j are automorphism of B^{n+1} , the sequence τ_j converges to an automorphism of B^{n+1} .

Let $q \in \overline{B^{n+1}}$ be the limit point of the sequence

$$\tau_j(p'_{m_j}) \rightarrow q \in \overline{B^{n+1}}.$$

We set

$$\lambda_j = \frac{\varepsilon_{m_j}}{\rho_{\varphi_j}}.$$

The sequence λ_j converges to the distance between the two distinct points q and $p \in bB^{n+1}$ so that there is a real number $e > 0$ such that

$$(8) \quad e^{-1} \leq |\lambda_j| \leq e,$$

if necessary, increasing e .

Let σ_j be a local automorphism in $Aut_{p_{m_j}}(bB^{n+1})$ defined by the normalizing parameters

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_{m_j}, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0.$$

Then the composition

$$\varphi_j'' \equiv \sigma_j^{-1} \circ \varphi_j \in Aut_{p_{m_j}}(bB^{n+1})$$

has the same normalizing parameters of the mapping φ_j except for $\rho_{\varphi_j''} = \lambda_j^{-1}$, i.e.,

$$U_{\varphi_j''} = U_{\varphi_j}, \quad \rho_{\varphi_j''} = \lambda_j^{-1}, \quad a_{\varphi_j''} = a_{\varphi_j}, \quad r_{\varphi_j''} = r_{\varphi_j}.$$

Therefore, by the estimates 5, 6, 7, 8, the sequence

$$\tau_j' \equiv \sigma_j^{-1} \circ \phi_{m_j} : B^{n+1} \rightarrow B^{n+1}$$

uniformly converges to an automorphism of B^{n+1} . This completes the proof. \square

Lemma 22. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD . Suppose that there is a connected open neighborhood U of a point $p \in bD$ and a biholomorphic mapping ϕ on U such that $\phi(U \cap bD) \subset bB^{n+1}$ and the inverse mapping ϕ^{-1} on bB^{n+1} is analytically continued along every chain of bB^{n+1} . Then the mapping ϕ is analytically continued to a biholomorphic mapping from D onto B^{n+1} .*

Proof. The chain on bB^{n+1} is characterized to be the intersection of a complex line on bB^{n+1} . Thus the chains on bB^{n+1} form a continuous family so that the analytic continuity of the inverse mapping ϕ^{-1} along every chain on bB^{n+1} is equivalent to the analytic continuity along any path on bB^{n+1} .

Note that the inverse mapping ϕ^{-1} is analytically continued along any path on bB^{n+1} and, by Hartogs extension theorem, the branching locus of a proper mapping cannot be bounded by bD . Since bB^{n+1} is simply connected, by the monodromy theorem, the mapping ϕ^{-1} is analytically continued to, by abuse of notation, a locally biholomorphic proper mapping $\phi^{-1} : B^{n+1} \rightarrow D$ such that $\phi^{-1}(bB^{n+1}) = bD$. By the fixed point property of the closed ball $\overline{B^{n+1}}$, the proper mapping $\phi^{-1} : B^{n+1} \rightarrow D$ is globally one-to-one so that the mapping $\phi^{-1} : B^{n+1} \rightarrow D$ is biholomorphic. This completes the proof. \square

Lemma 23. *Let D be a domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD and U be a connected open neighborhood of a point $p \in bD$. For a chain γ on bD passing through the point p and tangential to the direction with an angle θ_γ with respect to a unit vector v_p at the point p perpendicular to the complex tangent hyperplane, we denote $|a_\gamma| \equiv |\tan \theta_\gamma|$. Then there is a real number $e > 0$ such that every chain γ passing through the point p with $|a_\gamma| \geq e$ is the boundary of a nonsingular analytic disk $\delta_\gamma \subset U \cap D$ such that*

$$\gamma = \overline{\delta_\gamma} \cap bD.$$

Proof. We take a biholomorphic mapping ϕ on the open set U , if necessary, shrinking U such that

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Every chain λ on bB^{n+1} is an intersection with a complex line π_λ such that

$$\lambda = \pi_\lambda \cap bB^{n+1}.$$

For a sufficiently large real number $e > 0$, each chain γ with $|a_\gamma| \geq e$ is obtain by the relation

$$\gamma = \phi^{-1}(\lambda)$$

where the chain λ on bB^{n+1} satisfies the condition

$$\pi_\lambda \cap B^{n+1} \subset \phi(U \cap D).$$

Then we take

$$\delta_\gamma = \phi^{-1}(\pi_\lambda \cap B^{n+1}).$$

This completes the proof. \square

Lemma 24 (First Dogginal Lemma). *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD and ϕ be a biholomorphic mapping on a connected open neighborhood U of a point $p \in bB^{n+1}$ satisfying*

$$\phi(U \cap bB^{n+1}) \subset bD.$$

Suppose that there is a chain-segment $\gamma : [0, 1] \rightarrow bB^{n+1}$ such that $\gamma(0) \in U \cap bB^{n+1}$ and the mapping ϕ is analytically continued along the subpath $\gamma[0, \tau]$ for all $\tau < 1$, but not the whole path $\gamma[0, 1]$ as a local biholomorphic mapping. Let π be the complex line containing the chain-segment $\gamma[0, 1]$. Then there is an open neighborhood V along the path $\gamma[0, 1]$ such that

1. $\gamma[0, \tau] \subset V$ for all $\tau < 1$,
2. $bV \cap \pi \cap B(\gamma(1); \delta)$ is an angle for a sufficient small $\delta > 0$, which contains the chain-segment $\gamma[0, 1]$,
3. $bV \cap bB^{n+1} \cap B(\gamma(1); \delta)$ is slanted paraboloid for a sufficiently small $\delta > 0$, which smoothly touches the complex tangent hyperplane at the point $\gamma(1)$,
4. the mapping ϕ is analytically continued on V as a local biholomorphic mapping.

Proof. By the analytic continuation of the mapping ϕ along the subpath $\gamma[0, \tau]$ for all $\tau < 1$, there is a path $\phi \circ \gamma : [0, 1) \rightarrow bD$. Then we consider the following sequences

$$\begin{aligned} p_j &= \gamma\left(1 - \frac{1}{j}\right), \quad \text{for } j \in \mathbb{N}^+, \\ p'_j &= \phi \circ \gamma\left(1 - \frac{1}{j}\right), \quad \text{for } j \in \mathbb{N}^+. \end{aligned}$$

Since bD is compact, there is a subsequence p'_{m_j} and a point $p' \in bD$ such that

$$p'_{m_j} \rightarrow p'.$$

By Theorem 18, the mapping ϕ^{-1} is analytically continued along the path $\phi \circ \gamma[0, 1) \subset bD$.

Let φ_j be the analytic continuation of the mapping ϕ^{-1} at the point p'_{m_j} along the path $\phi \circ \gamma[0, 1) \subset bD$. By Theorem 18, there is an open neighborhood W of the point p' such that φ_j is locally biholomorphic on an open neighborhood of $W \cap bD$.

By Lemma 14, we may assume that φ_j is holomorphic on $W \cap D$, if necessary, shrinking W .

Since bD is spherical, there is an open neighborhood W of the point p' , if necessary, shrinking W , and a biholomorphic mapping φ on W such that

$$\varphi(W \cap bD) \subset bB^{n+1}.$$

Then, by Lemma 17, the compositions

$$\phi_j \equiv \varphi_j \circ \varphi^{-1} : \varphi(W) \cap bB^{n+1} \subset bB^{n+1}$$

are analytically continued, by abuse of notation, to automorphisms ϕ_j of the unit ball B^{n+1} . Without loss of generality, we may assume that the sequence ϕ_j converges to a holomorphic mapping uniformly on every compact subset of B^{n+1} .

We set

$$p''_{m_j} \equiv \varphi(p'_{m_j}) \in bB^{n+1} \quad \text{and} \quad p'' \equiv \varphi(p')$$

so that

$$p''_{m_j} \rightarrow p''.$$

Hence the relation

$$\phi_j(p''_{m_j}) = p_{m_j}$$

yields

$$\phi_j(p''_{m_j}) \rightarrow p.$$

By Lemma 9, the mapping ϕ_j converges to either a constant mapping or an automorphism of B^{n+1} . We claim that the sequence ϕ_j converges to the point p uniformly on every compact subset of B^{n+1} . Otherwise, the sequence ϕ_j converges to an automorphism of B^{n+1} so that the sequence

$$\varphi_j = \phi_j \circ \varphi$$

converges to a biholomorphic mapping on an open neighborhood W of the point p' . Then there is a real number δ such that the mapping φ_j and its inverse φ_j^{-1} are analytically continued respectively on

$$B(p'_{m_j}; \delta) \quad \text{and} \quad B(p_{m_j}; \delta)$$

as a locally biholomorphic mapping. Thus the mapping $\phi = \varphi_j^{-1}$ is biholomorphic on $B(p_{m_j}; \delta)$ for every point $p_{m_j} \rightarrow p$. This is impossible by the hypothesis on the mapping ϕ . Thus, by Lemma 9, the sequence ϕ_j converges to the point p on every compact subset of B^{n+1} .

Let π_j be the complex line passing through the two points p and p_{m_j} , and δ_j be the analytic disk

$$\delta_j = \pi_j \cap B^{n+1}.$$

Let ε_j be the euclidean length between the two points p and p_{m_j} . Note that the area $|\phi_j^{-1}(\delta_j)|$ of the analytic disk

$$\phi_j^{-1}(\delta_j)$$

is bounded from the below. Otherwise, by Lemma 23, the mapping $\phi = \varphi_j^{-1}$ is analytically continued over the point p as a locally biholomorphic mapping. Therefore, by First Scaling Lemma, there is a sequence $\sigma_j \in \text{Aut}_{p_{m_j}}(bB^{n+1})$ such that

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_j, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0$$

and the sequence

$$\psi_j \equiv \sigma_j^{-1} \circ \phi_j$$

converges to an automorphism of B^{n+1} .

Note that there is a real number $\delta > 0$ such that the mapping φ and its inverse φ^{-1} are biholomorphically continued respectively on

$$B(p'_{m_j}; \delta) \quad \text{and} \quad B(p''_{m_j}; \delta),$$

if necessary, passing to a subsequence. Further, there is a real number $\delta > 0$ such that the mapping ψ_j and its inverse ψ_j^{-1} are biholomorphically continued respectively to

$$B(p'_{m_j}; \delta) \quad \text{and} \quad B(p_{m_j}; \delta),$$

if necessary, shrinking δ . Then the mapping

$$\begin{aligned} \phi &= \varphi_j^{-1} \\ &= \varphi^{-1} \circ \psi_j^{-1} \circ \sigma_j^{-1} \end{aligned}$$

is biholomorphically continued on the open neighborhood

$$\sigma_j(B(p_{m_j}; \delta)).$$

For a canonical normalizing mapping $\mu_{p_{m_j}}$, we obtain

$$\sigma'_j \equiv \mu_{p_{m_j}} \circ \sigma_j \circ \mu_{p_{m_j}}^{-1} : \begin{cases} z^* = \sqrt{\varepsilon_j} z \\ w^* = \varepsilon_j w \end{cases}.$$

Since $p_{m_j} \rightarrow p$, by Lemma 5, there is a real number $\delta > 0$ such that the mapping $\mu_{p_{m_j}}$ and its inverse $\mu_{p_{m_j}}^{-1}$ are biholomorphically continued respectively to

$$B(p_{m_j}; \delta) \quad \text{and} \quad B(0; \delta).$$

Hence the mapping

$$\phi \circ \mu_{p_{m_j}}^{-1} = \varphi^{-1} \circ \psi_j^{-1} \circ \mu_{p_{m_j}}^{-1} \circ \sigma_j'^{-1}$$

is biholomorphically continued on

$$\sigma'_j(B(0; \delta)).$$

Since $p_{m_j} \rightarrow p$, by Lemma 5, the canonical normalizing mapping $\mu_{p_{m_j}}$ uniformly converges to the mapping μ_p so that the mapping ϕ is biholomorphically continued near the point p_{m_j} on

$$\mu_{p_{m_j}}^{-1} \circ \sigma'_j(B(0; \delta)).$$

Therefore, the analytically continued region of the mapping ϕ along the chain $\gamma[0, 1] \subset bB^{n+1}$ contains an open set along the chain $\gamma[0, 1]$ which touches to the point $\gamma(1)$ by an edge shape transversal to bB^{n+1} and by a slanted paraboloid shape on bB^{n+1} . This completes the proof. \square

1.3. Doggaebi variety on a sphere. Let ϕ be a biholomorphic mapping on an open neighborhood U of a point $p \in bD$ satisfying $\phi(U \cap bD) \subset bB^{n+1}$. Let $L \subset bB^{n+1}$ be the singular locus of the analytic continuation of the mapping ϕ^{-1} , which shall be called the Doggaebi variety associated to the mapping ϕ .

Lemma 25 (Second Scaling Lemma). *Let p be a point of the boundary bB^{n+1} and $p_j, j \in \mathbb{N}^+$, be a sequence of points of bB^{n+1} such that $p_j \neq p$ for all j and $p_j \rightarrow p$ as $j \rightarrow \infty$ to a direction tangential to the complex tangent hyperplane at the point $p \in bB^{n+1}$. Let ε_j be the euclidean distance between the two points p_j and p , and δ_j be the analytic disk*

$$\delta_j = \pi_j \cap B^{n+1}$$

where π_j is the complex line passing through the two points p_j and p . Suppose that there is a sequence p'_j of points of bB^{n+1} satisfying

$$p'_j \rightarrow p' \in bB^{n+1},$$

and a sequence of biholomorphic automorphisms $\phi_j \in \text{Aut}(B^{n+1})$ satisfying

$$\phi_j(p'_j) = p_j$$

such that the area $|\phi_j^{-1}(\delta_j)|$ of the analytic disks

$$\phi_j^{-1}(\delta_j)$$

is bounded from the below, i.e., there is a real number $c > 0$ satisfying

$$|\phi_j^{-1}(\delta_j)| \geq c.$$

Then there is a subsequence ϕ_{m_j} and a sequence of local automorphisms $\sigma_j \in \text{Aut}_{p_{m_j}}(bB^{n+1})$ such that

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_{m_j}^2, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0$$

and the composition

$$\sigma_j^{-1} \circ \phi_{m_j} : B^{n+1} \rightarrow B^{n+1}$$

uniformly converges to an automorphism of the unit ball B^{n+1} .

Proof. Note that there is a subsequence ϕ_{m_j} which converges to the point $p \in bB^{n+1}$ uniformly on an open neighborhood of the closed ball $\overline{B^{n+1}}$. We take a point $p'' \in bB^{n+1}$ such that $p'' \neq p$ and

$$p'' \notin \overline{\{p_{m_j} : j \in \mathbb{N}^+\}},$$

if necessary, passing to a subsequence.. Then, by Corollary 8, there is a unique decomposition of the automorphism ϕ_{m_j} such that

$$\phi_{m_j} = \varphi_j \circ \psi_j$$

where

$$\varphi_j \in \text{Aut}_{p_{m_j}}(bB^{n+1}), \quad \psi_j \in \text{Aut}_{p''}(bB^{n+1})$$

and the local automorphism ψ_j acts trivially on the tangent hyperplane of bB^{n+1} at the fixed point p' .

Let $U_{\psi_j}, \rho_{\psi_j}, a_{\psi_j}, r_{\psi_j}$ be the normalizing parameters of the local automorphism ψ_j . Since the local automorphism ψ_j acts trivially on the tangent hyperplane of bB^{n+1} at the fixed point p'' , we obtain

$$U_{\psi_j} = id_{n \times n}, \quad \rho_{\psi_j} = 1.$$

Since the sequence ϕ_{m_j} uniformly converges to the point p , there is a real number $e > 0$ such that

$$(9) \quad |a_{\psi_j}| \leq e, \quad |r_{\psi_j}| \leq e.$$

Let π_j be the complex line passing through the two points p and p_{m_j} , and δ_j be the analytic disks

$$\delta_j = \pi_j \cap B^{n+1}.$$

Let σ_j be a local automorphism in $Aut_{p_{m_j}}(bB^{n+1})$ defined by the normalizing parameters

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_{m_j}^2, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0.$$

Since the points p_j converges to the point p to a direction tangential to the complex tangent hyperplane at the point $p \in bB^{n+1}$, the area $|\sigma_j^{-1}(\delta_j)|$ of the analytic disk

$$\sigma_j^{-1}(\delta_j)$$

is bounded from below.

Let $U_{\varphi_j}, \rho_{\varphi_j}, a_{\varphi_j}, r_{\varphi_j}$ be the normalizing parameters of the local automorphism φ_j . Note that the analytic disk

$$\phi_{m_j}^{-1}(\delta_j)$$

is mapped by $\sigma_j^{-1} \circ \phi_{m_j}$ onto the analytic disk

$$\sigma_j^{-1}(\delta_j)$$

where the areas of the analytic disks in both classes are bounded from below. Further, the normalizing parameters $a_{\varphi'_j}, r_{\varphi'_j}$ of the composition $\varphi'_j = \sigma_j^{-1} \circ \varphi_j$ is the same value of $a_{\varphi_j}, r_{\varphi_j}$, i.e.,

$$a_{\varphi'_j} = a_{\varphi_j}, \quad r_{\varphi'_j} = r_{\varphi_j}$$

so that there is a real number $e > 0$, if necessary, increasing e , such that

$$(10) \quad |a_{\varphi_j}| \leq e.$$

Since the area of the analytic disks $\sigma_j^{-1}(\delta_j)$ is bounded by a positive number, the point p should be attracted to the center of the local automorphism $Aut_{p_{m_j}}(bB^{n+1})$. Hence, by passing to a subsequence, if necessary and increasing e , there is a real number $e > 0$ such that

$$(11) \quad |r_{\varphi_j}| \leq e$$

and

$$\rho_{\varphi_j} \rightarrow 0 \quad \text{as } j \rightarrow \infty.$$

Since bB^{n+1} is strongly pseudoconvex, we obtain

$$|U_{\varphi_j}| = 1.$$

We set

$$\lambda_j = \frac{\varepsilon_{m_j}^2}{\rho_{\varphi_j}}$$

so that there is a real number $e > 0$ such that

$$(12) \quad e^{-1} \leq |\lambda_j| \leq e,$$

if necessary, increasing e . Then the composition

$$\varphi'_j \equiv \sigma_j^{-1} \circ \varphi_j \in \text{Aut}_{p_{m_j}}(bB^{n+1})$$

has the same normalizing parameters of the mapping φ_j except for $\rho_{\varphi'_j} = \lambda_j^{-1}$, i.e.,

$$U_{\varphi'_j} = U_{\varphi_j}, \quad \rho_{\varphi'_j} = \lambda_j^{-1}, \quad a_{\varphi'_j} = a_{\varphi_j}, \quad r_{\varphi'_j} = r_{\varphi_j}.$$

Therefore, by the estimates 9, 10, 11, 12, the sequence

$$\tau_j \equiv \sigma_j^{-1} \circ \phi_{m_j} : B^{n+1} \rightarrow B^{n+1}$$

uniformly converges to an automorphism of B^{n+1} . This completes the proof. \square

Theorem 26. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD . Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ satisfying*

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Then the Doggaebi variety L associated to the mapping ϕ is a finite subset of bB^{n+1} such that the inverse mapping ϕ^{-1} is analytically continued along any piecewise chain curve on $bB^{n+1} \setminus L$ as a locally biholomorphic mapping.

Proof. By First Dogginal Lemma, the singular locus of the analytic continuation of the inverse mapping ϕ^{-1} on bB^{n+1} is an integral manifold of the subdistribution of the complex tangent hyperplanes on bB^{n+1} in its smooth part. Thus the mapping ϕ^{-1} cannot be branched on bB^{n+1} by a branching locus passing through the boundary bB^{n+1} . Otherwise, the intersection of the nontrivial branch of the mapping ϕ^{-1} to the boundary bB^{n+1} would be a nontrivial complex submanifold on bB^{n+1} . Hence the singular locus of the analytic continuation of the mapping ϕ^{-1} is well defined so that the inverse mapping ϕ^{-1} is analytically continued on $bB^{n+1} \setminus L$ as a locally biholomorphic mapping.

We take a chain-segment $\gamma : [0, 1] \rightarrow bB^{n+1}$ with $\gamma(1) = p \in L$ such that a germ of the mapping ϕ^{-1} at the point $\gamma(0)$ is analytically continued along all subpath $\gamma[0, \tau]$ with $\tau < 1$, but not the whole path $\gamma[0, 1]$. Note that the distribution of the complex tangent hyperplanes on bB^{n+1} is maximally nonintegrable. Thus, by First Dogginal Lemma, the singular locus L of the analytic continuation of the mapping ϕ^{-1} cannot bound the open region of the analytic continuation of the mapping ϕ^{-1} . Then the mapping ϕ^{-1} is analytically continued on the opposite side of the complex tangent hyperplane H_p at the point $p \in bB^{n+1}$. Thus there is a complex line π passing through the point p and an open neighborhood U of the point p such that

$$\pi \cap bB^{n+1}$$

is a chain on bB^{n+1} satisfying

$$L \cap U \cap \pi \cap bB^{n+1} = \{p\}.$$

We claim that, if necessary, shrinking U ,

$$L \cap U \cap bB^{n+1} = \{p\}$$

so that the singular locus L is a finite set on bB^{n+1} . By First Dogginal Lemma, there is a sequence $p_j \in bB^{n+1} \setminus L$ such that $p_j \rightarrow p$ and the sequence p_j converges to the point p to a direction tangential to the complex tangent hyperplane at the point $p \in L \subset bB^{n+1}$. Since bD is compact, there is a subsequence p_{m_j} and a point $p' \in bD$ such that

$$p'_{m_j} \equiv \phi^{-1}(p_{m_j}) \rightarrow p'.$$

Let ϕ_j be the germ of the mapping ϕ at the point $p'_{m_j} \in bD$ such that

$$\phi_j(p'_{m_j}) = p_{m_j}.$$

Since bD is spherical, there is an open neighborhood W of the point p' and a biholomorphic mapping ψ on W such that

$$\psi(W \cap bD) \subset bB^{n+1}.$$

Then the compositions $\varphi_j \equiv \phi_j \circ \psi^{-1}$ satisfy

$$\varphi_j(\psi(W) \cap bB^{n+1}) \subset bB^{n+1},$$

if necessary, shrinking W so that, by abuse of notation, the mapping φ_j is an automorphism of the unit ball B^{n+1} .

Let π_j be the complex line passing through the points p_{m_j} and p , and δ_j be the analytic disk

$$\delta_j = \pi_j \cap B^{n+1}.$$

Note that the area $|\varphi_j^{-1}(\delta_j)|$ of the analytic disk $\varphi_j^{-1}(\delta_j)$ is bounded from the below. Otherwise, $p \in bB^{n+1} \setminus L$. Further, the sequence φ_j converges to the point p uniformly on every compact subset of B^{n+1} , if necessary, passing to a subsequence. Otherwise, the sequence φ_j converges to an automorphism of the unit ball B^{n+1} so that $p \in bB^{n+1} \setminus L$. Let ε_j be the euclidean length between the two points p and p_{m_j} . Then, by Second Scaling Lemma, there is a sequence of local automorphisms $\sigma_j \in \text{Aut}_{p_{m_j}}(bB^{n+1})$ such that

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_j^2, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0$$

and the composition

$$\tau_j \equiv \sigma_j^{-1} \circ \varphi_j : B^{n+1} \rightarrow B^{n+1}$$

uniformly converges to an automorphism of the unit ball B^{n+1} . Thus there is a positive real number $\delta > 0$ such that the mapping τ_j and its inverse τ_j^{-1} are analytically continued respectively on

$$B(p''_{m_j}; \delta) \quad \text{and} \quad B(p_{m_j}; \delta)$$

where

$$p''_{m_j} = \psi(p'_{m_j}).$$

Therefore the mapping ϕ^{-1} at the point p_{m_j} :

$$\begin{aligned}\phi^{-1} &= \phi_j^{-1} \\ &= \psi^{-1} \circ \tau_j^{-1} \circ \sigma_j^{-1}\end{aligned}$$

is analytically continued to the open neighborhood

$$\sigma_j(B(p_{m_j}; \delta)).$$

By the canonical normalizing mapping $\mu_{p_{m_j}}$, we obtain

$$\sigma'_j \equiv \mu_{p_{m_j}} \circ \sigma_j \circ \mu_{p_{m_j}}^{-1} : \begin{cases} z^* = \varepsilon_j z \\ w^* = \varepsilon_j^2 w \end{cases}.$$

Hence the mapping ϕ^{-1} at the point p_{m_j} is analytically continued to the open neighborhood

$$\mu_{p_{m_j}}^{-1} \circ \sigma'_j(B(0; \delta)),$$

if necessary, shrinking δ . Since ε_j is the euclidean length between the two points p and p_{m_j} , the mapping ϕ^{-1} is analytically continued on an open region which touches to the point p to a converging direction to the sequence p_j by an edge shape tangential to the complex tangent hyperplane H_p at the point p and a $\sqrt{|x|}$ curve shape normal to H_p on bB^{n+1} .

Therefore, the singular locus L of the analytic continuation of the mapping ϕ^{-1} is isolated to the direction of the complex tangent hyperplane at each point of L . Since the boundary bB^{n+1} is compact, the singular locus L is a finite subset of bB^{n+1} . This completes the proof. \square

Lemma 27. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD . Then every chain on bD is extended each direction infinitely in its euclidean length.*

Proof. Suppose that the assertion is not true. Then there would be a path $\gamma : [0, 1] \rightarrow bD$ such that the subpath $\gamma[0, \tau]$ is a chain-segment for all $\tau < 1$ but the whole path $\gamma[0, 1]$ is not a chain segment.

Since bD is spherical, by definition, there exist a connected open neighborhood U of the point $\gamma(1)$ and a biholomorphic mapping ϕ on U such that $\phi(U \cap bD) \subset bB^{n+1}$. There is a unique closed circle χ on bB^{n+1} such that χ is a chain on bB^{n+1} and $\phi \circ \gamma[0, \tau] \subset \chi$ for all $\tau < 1$ (cf. [Pa3]).

Then the inverse image $\phi^{-1}(\chi \cap \phi(U))$ under the biholomorphic mapping ϕ is a chain on bB^{n+1} (cf. [Pa3]) such that

$$\gamma[0, 1] \cap U \subset \phi^{-1}(\chi \cap \phi(U)).$$

This is a contradiction. This completes the proof. \square

Theorem 28. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical real analytic boundary bD . Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ satisfying*

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Let E be the path space of bD pointed at the point $p \in bD$ mod homotopic relation so that E be a universal covering of bD with a natural CR structure and a natural

CR covering map $\psi : E \rightarrow bD$. Then there is a unique CR equivalence $\varphi : E \rightarrow bB^{n+1} \setminus L$ commuting the diagram

$$\begin{array}{ccc} E & & \\ \downarrow \psi & \searrow \varphi & \\ bD & \xrightarrow{\phi} & bB^{n+1} \setminus L \end{array}$$

where $L \subset bB^{n+1}$ is the Doggaebi variety associated to the mapping ϕ .

Proof. We obtain the set $bB^{n+1} \setminus L$ when the mapping ϕ is analytically continued along chains on bD . Since the mapping $\varphi : E \rightarrow bB^{n+1}$ is naturally induced by the analytic continuation of the mapping ϕ on bD (cf. Theorem 18), we obtain

$$bB^{n+1} \setminus L \subset \varphi(E)$$

Let $\gamma : [0, 1] \rightarrow bD$ be a path such that $\gamma(0) = p$. Then, for a sufficiently small $\varepsilon > 0$, there is an ε open neighborhood V of the path $\gamma[0, 1]$ such that the mapping ϕ is analytically continued on V as a local biholomorphic mapping. Then we take a piecewise chain curve $\eta : [0, 1] \rightarrow bD$ (cf. [Pa3]) such that

$$\eta(0) = \gamma(0), \quad \eta(1) = \gamma(1)$$

and

$$\eta[0, 1] \subset V.$$

Further, we may take a continuous function $\Gamma : [0, 1] \times [0, 1] \rightarrow V$ such that

$$\Gamma(0, \tau) = \gamma(\tau), \quad \Gamma(1, \tau) = \eta(\tau) \quad \text{for } \tau \in [0, 1]$$

and $\Gamma(\cdot, \tau) : [0, 1] \rightarrow V$ is a chain-segment for all $\tau \in [0, 1]$. Note that every chain-segment in this construction is finite in its euclidean length. By Lemma 27, the mapping ϕ is analytically continued along the whole path $\gamma[0, 1]$.

Then the image of E under the mapping φ satisfies

$$\varphi(E) \subset bB^{n+1} \setminus L$$

which yields

$$\varphi(E) = bB^{n+1} \setminus L.$$

Since the mapping ϕ^{-1} is analytically continued on $bB^{n+1} \setminus L$, the mapping $\varphi : E \rightarrow bB^{n+1}$ is a CR equivalence. This completes the proof. \square

Corollary 29. *Let D be a bounded domain with spherical real analytic boundary bD . Then there is a natural embedding*

$$\text{Aut}(D) \subset \text{Aut}(B^{n+1}).$$

Proof. Let E be the path space of bD pointed at the point $p \in bD$ mod homotopy so that E be a universal covering of bD with a natural CR structure and a natural CR covering map $\psi : E \rightarrow bD$. Then we take a biholomorphic mapping ϕ on an open neighborhood U of a point $p \in bD$ such that

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Let L be the Doggaebi variety associated to the mapping ϕ . Then, by Theorem 28, the analytic continuation of the mapping ϕ yields a natural CR equivalence

$$\text{Aut}(E) \simeq \text{Aut}(bB^{n+1} \setminus L).$$

Note that

$$\text{Aut}(D) = \text{Aut}(bD) \subset \text{Aut}(E) \simeq \text{Aut}(bB^{n+1} \setminus L) \subset \text{Aut}(bB^{n+1}) = \text{Aut}(B^{n+1}).$$

This completes the proof. \square

Lemma 30. *Let D, D' be bounded domains in \mathbb{C}^{n+1} with spherical real analytic boundaries bD, bD' , and $\phi : D \rightarrow D'$ be a proper holomorphic mapping. Suppose that there is an open neighborhood U of a point $p \in bD$ such that the mapping ϕ is analytically continued on U . Then the mapping ϕ is analytically continued along any path on bD as a locally biholomorphic mapping so that $\phi : D \rightarrow D'$ is locally biholomorphic.*

Proof. We may obtain the result by the boundary regularity of Lemma 16 and the transformation formula for a complex Monge-Ampere equation. Here we may give an independent proof. Note that

$$\phi(U \cap bD) \subset bD'$$

so that, by shrinking U , if necessary, the mapping ϕ is biholomorphic on U . By shrinking U , if necessary, we take biholomorphic mappings φ, φ' respectively on $U, \phi(U)$ such that

$$\begin{aligned} \varphi(U \cap bD) &\subset bB^{n+1} \\ \varphi'(\phi(U) \cap bD') &\subset bB^{n+1}. \end{aligned}$$

Then there are Doggaebi varieties L, L' on bB^{n+1} such that the inverses $\varphi^{-1}, \varphi'^{-1}$ are analytically continued respectively on $bB^{n+1} \setminus L$ and $bB^{n+1} \setminus L'$ as a local biholomorphic mapping. Note that the composition $\psi = \varphi' \circ \phi \circ \varphi^{-1}$ satisfies the relation

$$\psi(\varphi(U) \cap bB^{n+1}) \subset bB^{n+1}.$$

By abuse of notation, the mapping ψ is an automorphism of bB^{n+1} which comments the following diagram:

$$\begin{array}{ccc} bB^{n+1} \setminus L & \xrightarrow{\psi} & bB^{n+1} \setminus L' \\ \downarrow \kappa & & \downarrow \kappa' \\ bD & \xrightarrow{\phi} & bD' \end{array}.$$

where $\kappa : bB^{n+1} \setminus L \rightarrow bD$ is the analytic continuation of the mapping φ^{-1} and $\kappa' : bB^{n+1} \setminus L' \rightarrow bD'$ is the analytic continuation of the mapping φ'^{-1} on the boundary bB^{n+1} .

We claim

$$L' \subset \psi(L)$$

so that the mapping ϕ is analytically continued along any path on bD as a locally biholomorphic mapping. Otherwise, there is a point $q' \in L'$ such that

$$q' \in L' \setminus \psi(L)$$

From the proof of First Scaling Lemma, there is a sequence $p'_j \in bD'$ with $p'_j \rightarrow p' \in bD'$ and a sequence φ'_j of the analytic continuation of the mapping φ' at the point p'_j with $q'_j \equiv \varphi'_j(p'_j) \rightarrow q' \in L' \setminus \psi(L)$ such that there is an open neighborhood V of the point p' such that the mapping φ'_j is biholomorphic on $V \cap D'$ and the sequence

φ'_j converges to the point r uniformly on every compact subset of $V \cap D'$. Since ψ is an automorphism of the unit ball B^{n+1} , we obtain

$$\lambda_j \equiv \kappa \circ \psi^{-1} \circ \varphi'_j : V \cap D' \rightarrow D$$

and

$$\phi \circ \lambda_j = id \quad \text{on } V \cap D'.$$

We set

$$p_j \equiv \lambda_j(p'_j) \in bD.$$

Since bD is compact, there is a subsequence $p_{m_j} \in bD$ and a point $p \in bD$ such that

$$p_{m_j} \rightarrow p.$$

Since ϕ is a proper mapping, the mapping ϕ is a globally finite covering so that there is an open neighborhood W of the point p such that

$$\lambda_{m_j} = \phi^{-1} \quad \text{on } \phi(W) \cap D.$$

Hence we obtain

$$\psi = \varphi'_{m_j} \circ \phi \circ \kappa$$

Since the mapping ψ is an automorphism of the unit ball B^{n+1} , there is a sequence $q_j \in bB^{n+1}$ such that

$$\psi(q_j) = q'_j.$$

Hence we obtain

$$\kappa(q_{m_j}) = p_{m_j}.$$

Note that there is a real number $\delta > 0$ such that

$$B(r; 2\delta) \cap bB^{n+1} \cap \psi(L) = \emptyset.$$

Passing to a subsequence, if necessary, we may assume

$$q_{m_j} \in \psi^{-1}(B(r; \delta)) \cap bB^{n+1}$$

so that there is a point $q \in bB^{n+1} \setminus L$ satisfying

$$q_{m_j} \rightarrow q.$$

Hence we set

$$\chi_{m_j} \equiv \psi^{-1} \circ \varphi'_{m_j} \circ \lambda_{m_j}^{-1}$$

and

$$\kappa \circ \chi_{m_j} = id.$$

Finally, we obtain

$$\varphi'_{m_j} = \psi \circ \chi_{m_j} \circ \lambda_{m_j}.$$

Note that there is a real number $\delta > 0$ that the mappings λ_{m_j} and the inverse mappings $\lambda_{m_j}^{-1}$ are analytically continued respectively on

$$B(p'_{m_j}; \delta) \quad \text{and} \quad B(p_{m_j}; \delta),$$

and the mappings χ_{m_j} and the inverse mappings $\chi_{m_j}^{-1}$ are analytically continued respectively on

$$B(p_{m_j}; \delta) \quad \text{and} \quad B(q_{m_j}; \delta),$$

and the mapping ψ and the inverse mapping ψ^{-1} are analytically continued respectively on

$$B(q_{m_j}; \delta) \quad \text{and} \quad B(q'_{m_j}; \delta),$$

Hence the mapping φ'_{m_j} and the inverse mappings $\varphi'^{-1}_{m_j} = \kappa'$ are analytically continued respectively on

$$B(p'_{m_j}; \delta) \quad \text{and} \quad B(q'_{m_j}; \delta),$$

as a locally biholomorphic mapping. Since $q'_{m_j} \rightarrow q'$, the mapping κ' is analytically continued to the point q' as a locally biholomorphic mapping so that

$$q' \in bB^{n+1} \setminus L'.$$

This is a contradiction so that

$$L' \subset \psi(L).$$

This completes the proof. \square

2. BOUNDED DOMAINS WITH SPHERICAL BOUNDARIES

2.1. Differentiable spherical boundary. Let D be a domain in \mathbb{C}^{n+1} , $n \geq 1$, with a differentiable boundary bD . The boundary bD shall be called spherical if, for each point $p \in bD$, there is a connected open neighborhood U of the point p and a biholomorphic mapping ϕ on $U \cap D$ such that

$$(13) \quad \phi \in H(U \cap D) \cap C^1(U \cap \overline{D}), \quad \phi(U \cap bD) \subset bB^{n+1}$$

and the induced mapping $\phi : U \cap bD \rightarrow bB^{n+1}$ is CR diffeomorphic.

Lemma 31. *Let U be a connected open neighborhood of a point $p \in bB^{n+1}$ and ϕ be a biholomorphic mapping on $U \cap B^{n+1}$ such that*

$$\phi \in H(U \cap B^{n+1}) \cap C^1(U \cap \overline{B^{n+1}}), \quad \phi(U \cap bB^{n+1}) \subset bB^{n+1}$$

and the induced mapping $\phi : U \cap bB^{n+1} \rightarrow bB^{n+1}$ is CR diffeomorphic. Then the mapping ϕ is analytically continued to an automorphism of the unit ball B^{n+1} .

Proof. By Lemma 13, the mapping ϕ is biholomorphic on U , if necessary, shrinking U . Then, by Lemma 17, we obtain the desired result. This completes the proof. \square

The chain on bB^{n+1} is defined to be the intersection on bB^{n+1} by a complex line. The family of chains on bB^{n+1} leaves invariant under the action of biholomorphic automorphisms of B^{n+1} . We define the chain on the spherical differentiable boundary bD of a domain D to be the inverse image of the chain on bB^{n+1} under the mapping 13. By Lemma 31, the chain on the spherical differentiable boundary bD is well defined so that a chain of a spherical differentiable boundary is mapped to a chain of another spherical differentiable boundary under any induced CR diffeomorphism.

Lemma 32. *Let D be a domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD . Suppose that there is a connected open neighborhood U of a point $p \in bD$ and a biholomorphic mapping ϕ on $U \cap D$ such that*

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D}), \quad \phi(U \cap bD) \subset bB^{n+1}.$$

Then the mapping ϕ is analytically continued along any path on bD as a local biholomorphic mapping.

Proof. Suppose that the assertion is not true. Then there would be a path $\gamma : [0, 1] \rightarrow bD$ such that $\gamma(0) \in U \cap bD$ and the germ of a biholomorphic mapping ϕ at the point $\gamma(0)$ is analytically continued along the subpath $\gamma[0, \tau]$ with all $\tau < 1$ as a local biholomorphic mapping, but not the whole path $\gamma[0, 1]$.

Thus we reduce the proof to a local problem near the point $\gamma(1) \in bD$. Then, by the definition, there is a connected open neighborhood V of the point $\gamma(1)$ and a biholomorphic mapping φ on $V \cap D$ such that

$$\varphi \in H(V \cap D) \cap C^1(V \cap \overline{D}), \quad \varphi(V \cap bD) \subset bB^{n+1}$$

and the induced mapping $\varphi : U \cap bD \rightarrow bB^{n+1}$ is CR diffeomorphic.

Then we consider the mapping

$$\phi \circ \varphi^{-1} \in H(\varphi(V \cap D)) \cap C^1(\varphi(V \cap \overline{D})), \quad \phi \circ \varphi^{-1}(\varphi(V \cap bD)) \subset bB^{n+1}$$

and the curve

$$\varphi \circ \gamma[0, 1] \cap \varphi(V \cap bD) \subset bB^{n+1}.$$

By Lemma 13, the remaining part of the proof repeats the proof of Lemma 18. This completes the proof. \square

Lemma 33 (First Dogginal Lemma). *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD and ϕ be a biholomorphic mapping on $U \cap D$ for a connected open neighborhood U of a point $p \in bB^{n+1}$ satisfying*

$$\phi \in H(U \cap B^{n+1}) \cap C^1(U \cap \overline{B^{n+1}}), \quad \phi(U \cap bB^{n+1}) \subset bD.$$

Suppose that there is an injective path $\gamma : [0, 1] \rightarrow bB^{n+1}$ such that $\gamma[0, 1] \subset bB^{n+1}$ is a chain-segment satisfying

$$\gamma(0) \in U \cap bB^{n+1}$$

and the mapping ϕ is analytically continued along the subpath $\gamma[0, \tau]$ for all $\tau < 1$, but not the whole path $\gamma[0, 1]$ as a local biholomorphic mapping. Let π be the complex line containing the chain-segment $\gamma[0, 1]$. Then there is an open neighborhood V along the path $\gamma[0, 1]$ such that

1. $\gamma[0, \tau] \subset V$ for all $\tau < 1$,
2. $bV \cap \pi \cap B(\gamma(1); \delta)$ is an angle for a sufficient small $\delta > 0$, which contains the chain-segment $\gamma[0, 1]$,
3. $bV \cap bB^{n+1} \cap B(\gamma(1); \delta)$ is paraboloid for a sufficiently small $\delta > 0$, which smoothly touches the complex tangent hyperplane at the point $\gamma(1)$,
4. the mapping ϕ is analytically continued on $V \cap B^{n+1}$ as a local biholomorphic mapping

$$\phi \in H(V \cap B^{n+1}) \cap C^1(V \cap \overline{B^{n+1}}).$$

Proof. By the analytic continuation of the mapping ϕ along the subpath $\gamma[0, \tau]$ for all $\tau < 1$, there is a path $\phi \circ \gamma : [0, 1) \rightarrow bD$. Then we consider the following sequences

$$\begin{aligned} p_j &= \gamma \left(1 - \frac{1}{j} \right), \quad \text{for } j \in \mathbb{N}^+, \\ p'_j &= \phi \circ \gamma \left(1 - \frac{1}{j} \right), \quad \text{for } j \in \mathbb{N}^+. \end{aligned}$$

Since bD is compact, there is a subsequence p'_{m_j} and a point $p' \in bD$ such that

$$p'_{m_j} \rightarrow p'.$$

Thus we reduce the proof to a local problem near the point $p' \in bD$. Then, by the definition, there is a connected open neighborhood W of the point p' and a biholomorphic mapping φ on $W \cap D$ such that

$$\varphi \in H(W \cap D) \cap C^1(W \cap \overline{D}), \quad \varphi(W \cap bD) \subset bB^{n+1}$$

and the induced mapping $\varphi : U \cap bD \rightarrow bB^{n+1}$ is CR diffeomorphic.

Then we consider the mapping

$$\phi^{-1} \circ \varphi^{-1} \in H(\varphi(W \cap D)) \cap C^1(\varphi(W \cap \overline{D})), \quad \phi^{-1} \circ \varphi^{-1}(\varphi(W \cap bD)) \subset bB^{n+1}.$$

By Lemma 13, the remaining part of the proof repeats the proof of Lemma 24. This completes the proof. \square

By Lemma 31 and Lemma 33, we obtain the following result by the same argument of the proof of Theorem 28.

Theorem 34. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD . Suppose that there is a biholomorphic mapping ϕ on $U \cap D$ for a connected open neighborhood U of a point $p \in bD$ satisfying*

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Let E be the path space of bD pointed at the point $p \in bD$ mod homotopy so that E be a universal covering of bD with a natural CR structure and a natural CR covering map $\psi : E \rightarrow bD$. Then there is a unique CR equivalence $\varphi : E \rightarrow bB^{n+1} \setminus L$ commuting the diagram

$$\begin{array}{ccc} E & & \\ \downarrow \psi & \searrow \varphi & \\ bD & \xrightarrow{\phi} & bB^{n+1} \setminus L \end{array}$$

where $L \subset bB^{n+1}$ is the Doggaebi variety associated to the mapping ϕ .

2.2. Second Dogginal Lemma. We have examined the analytic continuation of a biholomorphic mapping ϕ from the spherical differentiable boundary bD of a bounded domain D into the boundary bB^{n+1} of the unit ball B^{n+1} . From now on, we shall examine the analytic continuation of the mapping ϕ into the domain D .

Lemma 35. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD . Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ satisfying*

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Then the inverse mapping ϕ^{-1} is analytically continued to a locally biholomorphic mapping from B^{n+1} into D .

Proof. By Theorem 34, there is a Doggaebi variety L on bB^{n+1} such that the mapping ϕ^{-1} is uniquely analytically continued on the set $bB^{n+1} \setminus L$. Then the mapping ϕ^{-1} is analytically continued to a holomorphic mapping on the unit ball B^{n+1} . Hence we have a holomorphic mapping $\varphi : B^{n+1} \rightarrow D$ which extends to the mapping $\phi^{-1} : bB^{n+1} \setminus L \rightarrow bD$. Note that the zero set of the determinant of the Jacobian matrix φ' of the mapping φ cannot be located on the set L on the boundary bB^{n+1} . Thus the mapping $\varphi : B^{n+1} \rightarrow D$ is locally biholomorphic. This completes the proof. \square

Lemma 36. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD and ϕ be a biholomorphic mapping on an open neighborhood U of a point $r \in bD$ satisfying*

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D}) \quad \text{and} \quad \phi(U \cap bD) \subset bB^{n+1}.$$

Let L be the Doggaebi variety associated to the mapping ϕ and $\varphi : B^{n+1} \rightarrow D$ be a locally biholomorphic mapping to be an analytic continuation of the mapping ϕ^{-1} . Suppose that there is a line segment $\gamma : [0, 1] \rightarrow D$ with

$$p = \gamma(1) \quad \text{and} \quad p_j = \gamma\left(1 - \frac{1}{j}\right)$$

and the germ of a locally biholomorphic mapping $\phi = \varphi^{-1}$ at the point $p_1 \equiv \gamma(0)$ is analytically continued along the subpath $\gamma[0, \tau]$ with all $\tau < 1$ as a locally biholomorphic mapping. Let $p'_j \equiv \phi(p_j) \in B^{n+1}$ be the sequence obtained by the analytic continuation of the mapping $\phi = \varphi^{-1}$ along the path $\gamma[0, 1)$. Then there is a subsequence p'_{m_j} and a point $p' \in L \subset bB^{n+1}$ such that the subsequence p'_{m_j} converges to the point p' to a direction transversal to the complex tangent hyperplane at the point $p' \in bB^{n+1}$.

Proof. Since the closed ball $\overline{B^{n+1}}$ is compact, there is a subsequence p'_{m_j} which converges to a point $p' \in \overline{B^{n+1}}$. Since the mapping φ is locally biholomorphic on B^{n+1} , the point p' should be on the boundary bB^{n+1} . Further, since $\varphi = \phi^{-1} : bB^{n+1} \setminus L \rightarrow bD$ is locally biholomorphic, we obtain

$$p'_{m_j} \rightarrow p' \in L.$$

Let π_p be the complex line containing the line segment $\gamma[0, 1]$. Since $p'_{m_j} \equiv \phi(p_{m_j})$, the analytic continuation of the mapping $\phi = \varphi^{-1}$ on the complex line π_p yields a complex curve $\varphi^{-1}(\pi_p \cap D)$ which touches the point $p' \in L \subset bB^{n+1}$. Since the mapping $\varphi : B^{n+1} \rightarrow D$ is locally biholomorphic up to the boundary subset $bB^{n+1} \setminus L$ and the boundary bB^{n+1} is strongly pseudoconvex, the extension

$$\varphi^{-1}(\pi_p \cap \overline{D})$$

of the complex curve $\varphi^{-1}(\pi_p \cap D)$ is transversal to the boundary bB^{n+1} near the point $p' \in L \subset bB^{n+1}$.

We claim that the extension $\varphi^{-1}(\pi_p \cap \overline{D})$ is transversal to the complex tangent hyperplane at the point $p' \in L$. We take a path $\lambda : [0, 1] \rightarrow bB^{n+1}$ such that

$p' = \lambda(1)$ and

$$\lambda[0, 1] \subset \overline{\varphi^{-1}(\pi_p \cap bD)} \cap bB^{n+1}.$$

Note that there are finitely many closed paths γ_j on bD such that

$$\pi_p \cap bD = \bigcup_j \gamma_j.$$

Since bD is strongly pseudoconvex, each path γ_j is transversal to the complex tangent hyperplane on bD at each point.

We consider the following sequence

$$q_j = \varphi \circ \lambda \left(1 - \frac{1}{j} \right) \in \pi_p \cap bD, \quad q'_j = \lambda \left(1 - \frac{1}{j} \right) \quad \text{for } j \in \mathbb{N}^+$$

such that

$$q'_j \rightarrow p' \quad \text{as } j \rightarrow \infty.$$

Since the set $\pi_p \cap bD$ is compact, there is a subsequence q_{m_j} and a point $q \in \pi_p \cap bD$ such that

$$q_{m_j} \rightarrow q \quad \text{as } j \rightarrow \infty.$$

Let ϕ_{m_j} be the germ of the analytic continuation of the mapping $\phi = \varphi^{-1}$ at the point q_{m_j} . By Theorem 18 and Lemma 14, we may assume that there is an open neighborhood W of the point q such that the mapping ϕ_{m_j} is holomorphic on $W \cap D$.

Since bD is spherical, there is a biholomorphic mapping ψ on W , if necessary, shrinking W , such that

$$\psi \in H(W \cap D) \cap C^1(W \cap \overline{D}) \quad \text{and} \quad \psi(W \cap bD) \subset bB^{n+1}.$$

We may assume that

$$q'' \equiv \psi(q) \neq p' \quad \text{and} \quad q''_{m_j} \equiv \psi(q_{m_j}).$$

Then, by Lemma 17, the composition

$$\eta_j \equiv \phi_{m_j} \circ \psi^{-1} \in \text{Aut}(B^{n+1})$$

are automorphisms of the unit ball B^{n+1} . Note that we have the condition

$$\eta_j(q''_{m_j}) = q'_{m_j} \rightarrow p'$$

and the sequence η_j converges to the point p' uniformly on every compact subset of B^{n+1} , if necessary, passing to a subsequence. Otherwise, $p' \notin L$.

Let π'_j be the complex line passing through the two points p' and q'_{m_j} , and δ'_j be the analytic disk

$$\delta'_j = \pi'_j \cap B^{n+1}.$$

The area $|\eta_j^{-1}(\delta'_j)|$ of the analytic disk $\eta_j^{-1}(\delta'_j)$ is bounded from the below. Otherwise, we would have $p' \notin L$. Then we decompose the mapping η_j as follows

$$\eta_j = \mu_j \circ \nu_j$$

where

$$\mu_j \in \text{Aut}_{q'_{m_j}}(bB^{n+1}), \quad \nu_j \in \text{Aut}_{p'}(bB^{n+1}).$$

Then, by First and Second Scaling Lemmas, we take a sequence of local automorphisms $\sigma_j \in \text{Aut}_{q'_{m_j}}(bB^{n+1})$ defined by the normalizing parameters

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \rho_{\mu_j}, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0.$$

Then the following sequence

$$\beta_j = \sigma_j^{-1} \circ \eta_j$$

converges to an automorphism of the unit ball B^{n+1} , if necessary, passing to a subsequence.

Let π_j be the complex line containing the tangent vector of the path

$$\psi(\varphi \circ \lambda[0, 1] \cap W) \subset bB^{n+1}$$

at the point q''_{m_j} , and δ_j be the analytic disk

$$\delta_j = \pi_j \cap B^{n+1}.$$

Clearly, the area $|\delta_j|$ of the analytic disk δ_j is bounded from the below. Note that, by the mapping $\sigma_j \in \text{Aut}_{q'_{m_j}}(bB^{n+1})$, the area $|\sigma_j^{-1}(\delta''_j)|$ of the analytic disk $\sigma_j(\delta''_j)$ is bounded from the below whenever the area $|\delta''_j|$ of the analytic disk δ''_j is bounded from the below. Thus the area $|\eta_j(\delta_j)|$ of the analytic disk

$$\eta_j(\delta_j) = \sigma_j \circ \beta_j(\delta_j)$$

is bounded from the below. Since the analytic disk $\eta_j(\delta_j)$ is the intersection of B^{n+1} and the complex line containing the tangent vector of the path $\lambda[0, 1]$ at the point

$$q'_{m_j} = \lambda\left(1 - \frac{1}{m_j}\right).$$

Thus the path $\lambda[0, 1]$ is transversal to the complex tangent hyperplane at the point $p' = \lambda(1)$. Therefore, the point p'_j approaches to the point $p' \in L$ to a direction transversal to the complex tangent hyperplane at the point $p' \in bB^{n+1}$. This completes the proof. \square

Lemma 37 (Second Dogginal Lemma). *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD and ϕ be a biholomorphic mapping on an open neighborhood U of a point $r \in bD$ satisfying*

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D}) \quad \text{and} \quad \phi(U \cap bD) \subset bB^{n+1}.$$

Let L be the Doggaebi variety associated to the mapping ϕ and $\varphi : B^{n+1} \rightarrow D$ be a locally biholomorphic mapping to be an analytic continuation of the mapping ϕ^{-1} . Suppose that there is a line segment $\gamma : [0, 1] \rightarrow D$ with

$$p = \gamma(1) \quad \text{and} \quad p_j = \gamma\left(1 - \frac{1}{j}\right)$$

and the germ of a locally biholomorphic mapping $\phi = \varphi^{-1}$ at the point $p_1 \equiv \gamma(0)$ is analytically continued along the subpath $\gamma[0, \tau]$ with all $\tau < 1$ as a locally biholomorphic mapping. Let $p'_j \equiv \phi(p_j) \in B^{n+1}$ be the sequence obtained by the analytic continuation of the mapping $\phi = \varphi^{-1}$ along the path $\gamma[0, 1)$. Suppose that there is a point $p' \in L \subset bB^{n+1}$ such that the sequence p'_j converges to the point p' to a direction transversal to the complex tangent hyperplane at the point $p' \in bB^{n+1}$.

Let π_p be the complex line containing the line segment $\gamma[0, 1]$. Then there is a distinguished complex hyperplane $H_p \subset T_p \mathbb{C}^{n+1}$ at the point $p \in D$ satisfying

$$T_p \mathbb{C}^{n+1} = H_p \oplus \pi_p$$

and an open neighborhood V of the line segment $\gamma[0, 1]$ such that

1. $bV \cap \pi_p \cap B(p; \delta)$ is an angle for a sufficient small $\delta > 0$, which contains the path $\gamma[0, 1]$,
2. $bV \cap R_p \cap B(p; \delta)$ is a slanted paraboloid for a sufficiently small $\delta > 0$, which smoothly touches the complex hyperplane H_p at the point p ,
3. the germ of a locally biholomorphic mapping $\phi = \varphi^{-1}$ at the point $p_1 \equiv \gamma(0)$ is analytically continued on V as a locally biholomorphic mapping,

where R_p is a real hyperplane containing the line segment $\gamma[0, 1]$ and

$$H_p \subset R_p.$$

Proof. We take a sequence of automorphisms $\phi_j \in \text{Aut}(B^{n+1})$ such that

$$\phi_j(p'_1) = p'_j \rightarrow p' \in L.$$

Then the composition $\tau_j \equiv \varphi \circ \phi_j : B^{n+1} \rightarrow D$ forms a normal family so that there is a subsequence $\tau_{m_j} \equiv \varphi \circ \phi_{m_j}$ which converges to a holomorphic mapping $\tau : B^{n+1} \rightarrow D$ uniformly on every compact subset of B^{n+1} .

We claim that τ is a locally biholomorphic mapping. We take a point $q \in bB^{n+1} \setminus L$ and $q'_{m_j} = \tau_{m_j}(q) \in bD$ such that

$$q'_{m_j} = \tau_{m_j}(q) \rightarrow q' \in bD,$$

if necessary, passing to a subsequence. Since bD is spherical, there is an open neighborhood W of the point q' and a biholomorphic mapping ψ on $W \cap D$ satisfying

$$\psi \in H(W \cap D) \cap C^1(W \cap \overline{D}) \quad \text{and} \quad \psi(W \cap bD) \subset bB^{n+1}.$$

Then we consider the composition $\chi_{m_j} \equiv \psi \circ \varphi \circ \phi_{m_j}$ so that, by Lemma 17 and by abuse of notation,

$$\chi_{m_j} \in \text{Aut}(B^{n+1}).$$

Suppose that the assertion is not true. Then the sequence χ_{m_j} converges to a boundary point $\psi(q') \in bB^{n+1}$ uniformly on every compact subset of B^{n+1} , if necessary, passing to a subsequence. Hence the sequence $\tau_{m_j} \equiv \varphi \circ \phi_{m_j}$ would converge to a boundary point $q' \in bD$ uniformly on every compact subset of B^{n+1} . By the way, note that

$$\tau_{m_j}(p'_1) = p_{m_j} \rightarrow p \in D.$$

This is a contradiction. Hence the holomorphic mapping τ is locally biholomorphic. Thus there is a real number $\delta > 0$ such that the mapping τ_{m_j} and the inverse $\tau_{m_j}^{-1}$ are analytically continued to a biholomorphic mapping respectively on

$$B(p_{m_j}; \delta), \quad B(p'_1; \delta).$$

Let ε_j be the euclidean length between the two points p' and p'_j . By First Scaling Lemma, there is a sequence of automorphisms

$$\sigma_j \in \text{Aut}_{p'}(bB^{n+1})$$

such that, for a subsequence ϕ_{m_j} ,

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_{m_j}, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0$$

and the composition

$$\eta_j \equiv \sigma_j^{-1} \circ \phi_{m_j}$$

uniformly converges to an automorphism of the unit ball B^{n+1} . Then there is a real number $\delta > 0$ such that the mapping η_j and the inverse η_j^{-1} are analytically continued respectively on

$$B(p'_1; \delta), \quad B(p''_{m_j}; \delta)$$

where

$$p''_{m_j} = \eta_j(p'_{m_j}).$$

Then we obtain

$$\varphi = \tau_{m_j} \circ \eta_j^{-1} \circ \sigma_j^{-1}.$$

Thus the mapping $\phi = \varphi^{-1}$ is analytically continued onto the open set

$$\tau_{m_j} \circ \eta_j^{-1} \left(\sigma_j \left(B(p''_{m_j}; \delta) \right) \right)$$

which is centered at the point p_{m_j} . For a canonical normalizing mapping $\mu_{p'}$, we obtain

$$\sigma'_j \equiv \mu_{p'} \circ \sigma_j \circ \mu_{p'}^{-1} : \begin{cases} z^* = \sqrt{\varepsilon_{m_j}} z \\ w^* = \varepsilon_{m_j} w \end{cases}.$$

We set

$$\mu_{p'}(p''_{m_j}) \rightarrow p''' \in \mu_{p'}(B^{n+1})$$

so that, shrinking $\delta > 0$, if necessary, the mapping $\phi = \varphi^{-1}$ is analytically continued onto the open set

$$\tau_{m_j} \circ \eta_j^{-1} \circ \mu_{p'}(\sigma'_j(B(p'''; \delta)))$$

which is centered at the point p_{m_j} .

Since ε_{m_j} is the euclidean distance between the two points p and p_{m_j} , the analytically continued region of the mapping $\phi = \varphi^{-1}$ along the line segment $\gamma[0, 1] \subset D$ contains an open set along the line segment $\gamma[0, 1]$ which touches to the point $p = \gamma(1)$ by an edge shape on the complex line π_p and by a slanted paraboloid shape on the real hyperplane R_p . This completes the proof. \square

Lemma 38. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD and ϕ be a biholomorphic mapping on an open neighborhood U of a point $r \in bD$ satisfying*

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D}) \quad \text{and} \quad \phi(U \cap bD) \subset bB^{n+1}.$$

Let L be the Doggaebi variety associated to the mapping ϕ and $\varphi : B^{n+1} \rightarrow D$ be a locally biholomorphic mapping to be an analytic continuation of the mapping ϕ^{-1} . Let H_p be the complex hyperplane at the point $p \in D$ in Lemma 37 and π_p be a complex line satisfying

$$T_p \mathbb{C}^{n+1} = H_p \oplus \pi_p.$$

Suppose that, along a line segment $\gamma : [0, 1] \rightarrow \pi_p \cap D$ with $p = \gamma(1)$, the germ of a locally biholomorphic mapping $\phi = \varphi^{-1}$ at the point $\gamma(0)$ is analytically continued along the subpath $\gamma[0, \tau]$ with all $\tau < 1$ as a locally biholomorphic mapping such that the limit point

$$\lim_{\tau \rightarrow 1} \phi \circ \gamma(\tau)$$

is the point $p' \in L \subset bB^{n+1}$ in Lemma 37. Then there is an open neighborhood V of the line segment $\gamma[0, 1)$ such that

1. $bV \cap \pi_p \cap B(p; \delta)$ is an angle for a sufficient small $\delta > 0$, which contains the path $\gamma[0, 1]$,
2. $bV \cap R_p \cap B(p; \delta)$ is a slanted paraboloid for a sufficiently small $\delta > 0$, which smoothly touches the complex hyperplane H_p at the point p ,
3. the germ of a locally biholomorphic mapping $\phi = \varphi^{-1}$ at the point $\gamma(0)$ is analytically continued on V as a locally biholomorphic mapping,

where R_p is a real hyperplane containing the line segment $\gamma[0, 1]$ and

$$H_p \subset R_p.$$

Proof. By Lemma 36, $\phi \circ \gamma(\tau)$ approaches to the point $p' \in L$ to a direction transversal to the complex tangent hyperplane at the point p' as $\tau \rightarrow 1$. Then there is a complex hyperplane H'_p satisfying the conditions in Lemma 37.

Note that the complex hyperplane H_p is determined by the mapping $\varphi : B^{n+1} \rightarrow D$ and the complex tangent hyperplane $H_{p'}$ at the point $p' \in L \subset bB^{n+1}$, but H_p does not depend on the approaching direction of $\phi \circ \gamma(\tau) \rightarrow p'$ as $\tau \rightarrow 1$. Thus $H'_p = H_p$. This completes the proof. \square

2.3. Biholomorphic equivalence.

Lemma 39. Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD and G be the path space of D mod homotopic relation so that G is a universal covering Riemann domain with a natural complex structure and a natural holomorphic covering map $\kappa : G \rightarrow D$. Suppose that there is a biholomorphic mapping

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D})$$

for a connected open neighborhood U of a point $p \in bD$ satisfying

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Then the analytic continuation of the inverse mapping ϕ^{-1} is lifted to a holomorphic mapping ψ from B^{n+1} onto G such that $\psi : B^{n+1} \rightarrow G$ is a proper locally biholomorphic mapping, i.e., a finite covering of G , satisfying the following relation:

$$\begin{array}{ccc} & G & \\ \psi \nearrow & & \downarrow \kappa \\ B^{n+1} & \xrightarrow{\varphi} & D \end{array}.$$

Proof. By Theorem 35, there is a locally biholomorphic mapping

$$\varphi : B^{n+1} \rightarrow D$$

such that φ is the analytic continuation of the mapping ϕ^{-1} and

$$\varphi = \phi^{-1} \quad \text{on} \quad bB^{n+1} \setminus L$$

where L is the Doggaebi variety associated to the mapping ϕ .

A piecewise line segment curve is a path $\gamma : [0, 1] \rightarrow D$ consisting of finitely many line segments. Fix a point $b \in U \cap D$. We shall show that the mapping ϕ is analytically continued along any piecewise line segment curve. Suppose that $\gamma : [0, 1] \rightarrow D$ be a piecewise line segment curve with $\gamma(0) = b$ such that the germ of the mapping ϕ at the point $\gamma(0)$ is analytically continued along all subpath $\gamma[0, \tau]$ with $\tau < 1$, but not the whole path $\gamma[0, 1]$. Let π_p be a complex line satisfying, for sufficiently small $\varepsilon > 0$,

$$\gamma[1 - \varepsilon, 1] \subset \pi_p.$$

Then, by Second Dogginal Lemma, there is a distinguished complex hyperplane H_p at the point $p = \gamma(1)$ satisfying

$$T_p \mathbb{C}^{n+1} = H_p \oplus \pi_p$$

and an open neighborhood V containing the line segment $\gamma[0, \tau]$ with all $\tau < 1$ such that

1. $bV \cap \pi_p \cap B(p; \varepsilon)$ is an angle for a sufficient small $\varepsilon > 0$, which contains the path $\gamma[0, 1]$,
2. $bV \cap R_p \cap B(p; \varepsilon)$ is a slanted paraboloid for a sufficiently small $\varepsilon > 0$, which smoothly touches the complex hyperplane H_p at the point p ,
3. the germ of a locally biholomorphic mapping $\phi = \varphi^{-1}$ at the point $\gamma(0)$ is analytically continued on V as a locally biholomorphic mapping,

where R_p is a real hyperplane satisfying, for sufficiently small $\varepsilon > 0$,

$$\gamma[1 - \varepsilon, 1] \subset R_p \quad \text{and} \quad H_p \subset R_p.$$

Thus we can find a sequence of points $p_j \in V \cap B(p; \varepsilon)$ and a sequence of germs ϕ_j of the analytic continuation of the mapping ϕ at the point p_j such that the sequence p_j converges to the point p to a direction tangential to the complex hyperplane H_p at the point p . We set

$$p'_j = \phi_j(p_j) \in B^{n+1}.$$

Then there is a point $p' \in L \subset bB^{n+1}$ such that $p'_j \rightarrow p'$ to a direction tangential to the complex tangent hyperplane at the point $p' \in bB^{n+1}$. We take a sequence of automorphisms $\varphi_j \in \text{Aut}(B^{n+1})$ such that

$$\varphi_j(p'_j) = p'_j \rightarrow p' \in L.$$

Then the composition $\tau_j \equiv \varphi \circ \varphi_j : B^{n+1} \rightarrow D$ forms a normal family so that there is a subsequence $\tau_{m_j} \equiv \varphi \circ \varphi_{m_j}$ which converges to a holomorphic mapping $\tau : B^{n+1} \rightarrow D$ uniformly on every compact subset of B^{n+1} .

We claim that τ is a locally biholomorphic mapping. We take a point $q \in bB^{n+1} \setminus L$ and $q'_{m_j} = \tau_{m_j}(q) \in bD$ such that

$$q'_{m_j} = \tau_{m_j}(q) \rightarrow q' \in bD,$$

if necessary, passing to a subsequence. Since bD is spherical, there is an open neighborhood W of the point q' and a biholomorphic mapping ψ on $W \cap D$ satisfying

$$\psi \in H(W \cap D) \cap C^1(W \cap \overline{D}) \quad \text{and} \quad \psi(W \cap bD) \subset bB^{n+1}.$$

Then we consider the composition $\chi_{m_j} \equiv \psi \circ \varphi \circ \varphi_{m_j}$ so that, by Lemma 17 and by abuse of notation,

$$\chi_{m_j} \in \text{Aut}(B^{n+1}).$$

Suppose that the assertion is not true. Then the sequence χ_{m_j} converges to a boundary point $\psi(q') \in bB^{n+1}$ uniformly on every compact subset of B^{n+1} , if necessary, passing to a subsequence. Hence the sequence $\tau_{m_j} \equiv \varphi \circ \varphi_{m_j}$ would converge to a boundary point $q' \in bD$ uniformly on every compact subset of B^{n+1} . By the way, note that

$$\tau_{m_j}(p'_1) = p_{m_j} \rightarrow p \in D.$$

This is a contradiction. Hence the holomorphic mapping τ is locally biholomorphic. Thus there is a real number $\delta > 0$ such that the mapping τ_{m_j} and the inverse $\tau_{m_j}^{-1}$ are analytically continued to a biholomorphic mapping respectively on

$$B(p_{m_j}; \delta), \quad B(p'_1; \delta).$$

Let ε_j be the euclidean length between the two points p' and p'_j . By Second Scaling Lemma, there is a sequence of automorphisms

$$\sigma_j \in \text{Aut}_{p'}(bB^{n+1})$$

such that, for a subsequence φ_{m_j} ,

$$U_{\sigma_j} = id_{n \times n}, \quad \rho_{\sigma_j} = \varepsilon_{m_j}^2, \quad a_{\sigma_j} = 0, \quad r_{\sigma_j} = 0$$

and the composition

$$\eta_j \equiv \sigma_j^{-1} \circ \varphi_{m_j}$$

uniformly converges to an automorphism of the unit ball B^{n+1} . Then there is a real number $\delta > 0$ such that the mapping η_j and the inverse η_j^{-1} are analytically continued respectively on

$$B(p'_1; \delta), \quad B(p''_{m_j}; \delta)$$

where

$$p''_{m_j} = \eta_j(p'_{m_j}).$$

Then we obtain

$$\varphi = \tau_{m_j} \circ \eta_j^{-1} \circ \sigma_j^{-1}.$$

Thus the mapping $\phi = \varphi^{-1}$ is analytically continued onto the open set

$$\tau_{m_j} \circ \eta_j^{-1} \left(\sigma_j \left(B(p''_{m_j}; \delta) \right) \right)$$

which is centered at the point p_{m_j} . For a canonical normalizing mapping $\mu_{p'}$, we obtain

$$\sigma'_j \equiv \mu_{p'} \circ \sigma_j \circ \mu_{p'}^{-1} : \begin{cases} z^* = \varepsilon_{m_j} z \\ w^* = \varepsilon_{m_j}^2 w \end{cases}.$$

We set

$$\mu_{p'}(p''_{m_j}) \rightarrow p''' \in \mu_{p'}(B^{n+1})$$

so that, shrinking $\delta > 0$, if necessary, the mapping $\phi = \varphi^{-1}$ is analytically continued onto the open set

$$\tau_{m_j} \circ \eta_j^{-1} \circ \mu_{p'} (\sigma'_j (B(p'''; \delta)))$$

which is centered at the point p_{m_j} .

Since the sequence p_{m_j} converges to p to a direction tangential to the complex hyperplane H_p at the point p , and ε_{m_j} is the euclidean distance between the two points p and p_{m_j} , the analytically continued region of the mapping $\phi = \varphi^{-1}$ along the sequence $p_{m_j} \in V \cap D$ contains an open set along the converging direction of the sequence p_{m_j} by an edge shape tangential to the complex hyperplane H_p at the point p and a $\sqrt{|x|}$ curve shape normal to H_p .

Thus there is a complex line π'_p satisfying

$$\pi'_p \subset H_p \quad \text{and} \quad p \in \pi'_p,$$

and an open neighborhood W of the point p such that the mapping ϕ is analytically continued on

$$W \cap \pi'_p.$$

Then we take a line segment $\gamma : [0, 1] \rightarrow \pi'_p \subset H_p$ such that

$$\gamma : [0, 1] \subset W \cap (\pi'_p \setminus p) \quad \text{and} \quad \gamma(1) = p.$$

Note that

$$\lim_{\tau \rightarrow 1} \phi \circ \gamma(\tau) = p' \in L \subset bB^{n+1}.$$

By Second Dogginal Lemma, the distinguished complex tangent hyperplane H_p satisfies

$$T_p \mathbb{C}^{n+1} = H_p \oplus \pi'_p$$

so that

$$\pi'_p \cap H_p = \{p\}.$$

This is a contradiction so that the germ of the mapping ϕ at the point $b \in U \cap D$ is analytically continued along the whole path $\gamma[0, 1]$. Hence the mapping ϕ is analytically continued along any piecewise line segment curve on D as a locally biholomorphic mapping.

We claim that the mapping $\phi : U \cap D \rightarrow B^{n+1}$ is analytically continued along any path on D as a locally biholomorphic mapping. Let $\gamma : [0, 1] \rightarrow D$ be a path on D . Then we take a piecewise line segment curve $\lambda : [0, 1]$ and a continuous function $\Gamma : [0, 1] \times [0, 1] \rightarrow D$ such that

$$\begin{aligned} \gamma(0) &= \lambda(0), \quad \gamma(1) = \lambda(1) \\ \Gamma(0, \tau) &= \gamma(\tau), \quad \Gamma(1, \tau) = \lambda(\tau) \quad \text{for all } \tau \in [0, 1] \end{aligned}$$

and the path $\Gamma(\cdot, \tau) : [0, 1] \rightarrow D$ for each $\tau \in [0, 1]$ is a piecewise line segment curve on D . Clearly, the mapping ϕ is analytically continued along the whole path $\gamma[0, 1]$ so that the mapping ϕ is analytically continued along any path on D as a locally biholomorphic mapping.

Let G be the path space of D pointed by a point of $U \cap D$ mod homotopic relation so that G is a universal covering of D with a natural complex structure and a natural holomorphic covering map $\kappa : G \rightarrow D$. By the analytic continuation of the mapping $\phi : U \cap D \rightarrow B^{n+1}$ on D , the mapping $\varphi : B^{n+1} \rightarrow D$ has its natural

proper locally biholomorphic lift $\psi : B^{n+1} \rightarrow G$. Since the mapping $\psi : B^{n+1} \rightarrow G$ is proper and locally biholomorphic, the mapping ψ is a finite covering of G . This completes the proof. \square

Theorem 40. *Let D be a bounded domain in \mathbb{C}^{n+1} with spherical differentiable boundary bD such that the fundamental group $\pi_1(D)$ is finite. Suppose that there is a biholomorphic mapping*

$$\phi \in H(U \cap D) \cap C^1(U \cap \overline{D})$$

for a connected open neighborhood U of a point $p \in bD$ satisfying

$$\phi(U \cap bD) \subset bB^{n+1}.$$

Then D is necessarily simply connected and the mapping ϕ is analytically continued to a biholomorphic mapping from D onto B^{n+1} .

Proof. Let G be the path space of D pointed by a point of $U \cap D$ mod homotopic relation with a natural complex structure and a natural locally biholomorphic covering map $\kappa : G \rightarrow D$. Then, by Lemma 39, there is a locally biholomorphic finite covering lift $\psi : B^{n+1} \rightarrow G$ satisfying

$$\varphi = \kappa \circ \psi$$

where $\varphi : B^{n+1} \rightarrow D$ is an analytic continuation of the inverse mapping ϕ^{-1} .

Since the fundamental group $\pi_1(D)$ is finite, the mapping $\kappa : G \rightarrow D$ is a finite covering. Thus the mapping

$$\varphi = \kappa \circ \psi : B^{n+1} \rightarrow D$$

is a locally biholomorphic finite covering. Therefore, the analytic continuation of the inverse mapping ϕ^{-1} on the boundary bB^{n+1} yields finitely many germs at each point of bB^{n+1} . By Lemma 20, the Doggaebi variety L associated to the mapping ϕ is empty so that the mapping

$$\varphi = \phi^{-1} : bB^{n+1} \rightarrow bD$$

is also a locally biholomorphic finite covering. Thus the mapping

$$\varphi : \overline{B^{n+1}} \rightarrow \overline{D}$$

is a finite covering mapping. Then the fixed point property of the close ball $\overline{B^{n+1}}$ implies that the mapping $\varphi : \overline{B^{n+1}} \rightarrow \overline{D}$ is a simple cover. Otherwise, a nontrivial deck transformation of the closed ball $\overline{B^{n+1}}$ yields a continuous function on $\overline{B^{n+1}}$ with no fixed point. Therefore, the analytic continuation of the mapping $\phi : U \cap D \rightarrow B^{n+1}$ is analytically continued to a biholomorphic mapping

$$\varphi^{-1} : D \rightarrow B^{n+1}.$$

This completes the proof. \square

3. LOCALLY BIHOLOMORPHIC MAPPINGS

3.1. Estimates of normalizing parameters.

Lemma 41. *Let M be a nonspherical analytic real hypersurface in \mathbb{C}^{n+1} and $Aut_p(M)$ be the isotropy subgroup at a point $p \in M$. Suppose that there is a real number $c \geq 1$ satisfying*

$$\sup_{\varphi \in Aut_p(M)} |U_\varphi| \leq c < \infty.$$

Then there is a real number $e \geq 1$ satisfying

$$|a_\phi| \leq e, \quad e^{-1} \leq |\rho_\phi| \leq e, \quad |r_\phi| \leq e$$

for every local automorphism $\phi \in Aut_p(M)$.

Proof. The real hypersurface $\mu_p(M)$ in normal form is expanded as follows:

$$v = \langle z, z \rangle + \sum_{k=4}^{\infty} F_k(z, \bar{z}, u)$$

where

$$F_k(\nu z, \nu \bar{z}, \nu^2 u) = \nu^k F_k(z, \bar{z}, u).$$

Since M is nonspherical, not all $F_k(z, \bar{z}, u)$ are zero. Then we make an estimate of the normalizing parameters $a_\phi, \rho_\phi, r_\phi$ for $\phi \in Aut_p(M)$ (cf. [Pa3]). This completes the proof. \square

Theorem 42. *Let M be a nonspherical strongly pseudoconvex analytic real hypersurface in a complex manifold. Then the local isotropy subgroup $Aut_p(M)$ is compact for every point $p \in M$.*

Proof. Because the situation is local, we may assume by taking a coordinate chart, if necessary, that the complex manifold is \mathbb{C}^{n+1} . Then the pseudoconvexity of M leads to

$$|U_\varphi| = 1 \quad \text{for } \varphi \in Aut_p(M).$$

By Lemma 41, we obtain the desired result. This completes the proof. \square

Lemma 43. *Let M, M' be nonspherical analytic real hypersurfaces in \mathbb{C}^{n+1} and p, p' be points respectively of M, M' such that the two germs M at p and M' at p' are biholomorphically equivalent. Suppose that the isotropy subgroup $Aut_p(M)$ is compact. Then there is a real number $\delta_p > 0$ such that each germ of a biholomorphic mapping ϕ sending the germ M at p to the germ M' at p' is analytically continued to the open ball $B(p; \delta_p)$.*

Proof. We take a biholomorphic mapping ϕ on a connected open neighborhood U of the point $p \in M$ such that

$$\phi(U \cap M) \subset M'.$$

Then every germ of a biholomorphic mapping sending the germ M at p to the germ M' at p' is one of the following

$$\phi \circ \varphi \quad \text{for } \varphi \in Aut_p(M).$$

Then the compactness of the group $Aut_p(M)$ leads to the desired result. This completes the proof. \square

Lemma 44. *Let M be a nonspherical analytic real hypersurface in \mathbb{C}^{n+1} such that the isotropy subgroup $Aut_p(M)$ is compact at every point $p \in M$. Then, for each compact subset $K \subset\subset M$, there is a real number $e \geq 1$ satisfying*

$$e^{-1} \leq |U_\phi| \leq e, \quad |a_\phi| \leq e, \quad e^{-1} \leq |\rho_\phi| \leq e, \quad |r_\phi| \leq e$$

for every point $p \in K$ and every local automorphism $\phi \in Aut_p(M)$.

Proof. The real hypersurface $\mu_p(M)$ in normal form is expanded as follows:

$$v = \langle z, z \rangle + \sum_{|I|, |J| \geq 2, k \geq 1} \lambda_{IJK}(p) z^I \bar{z}^J u^k.$$

Suppose that the normalization N_e , $e = (U, a, \rho, r) \in H$, transforms the real hypersurface $\mu_p(M)$ to a real hypersurfaces expanded as follows:

$$v = \langle z, z \rangle + \sum_{|I|, |J| \geq 2, k \geq 1} \eta_{IJK}(p; U, a, \rho, r) z^I \bar{z}^J u^k.$$

Note that the element $(U_\phi, a_\phi, \rho_\phi, r_\phi)$ for $\phi \in Aut_p(M)$ is characterized by the following equalities:

$$\lambda_{IJK}(p) = \eta_{IJK}(p; U, a, \rho, r), \quad |I|, |J| \geq 2, k \geq 1.$$

Then, since the algebraic subset of (U, a, ρ, r) is characterized by finitely many equalities, there is an integer K such that the following equalities

$$(14) \quad \lambda_{IJK}(p) = \eta_{IJK}(p; U, a, \rho, r), \quad |I|, |J|, k \leq K$$

characterize the element $(U_\phi, a_\phi, \rho_\phi, r_\phi)$ for $\phi \in Aut_p(M)$.

Since the isotropy subgroup $Aut_p(M)$ is compact, there is a real number $e_p \geq 1$ such that

$$e_p^{-1} \leq |U_\phi| \leq e_p, \quad |a_\phi| \leq e_p, \quad e_p^{-1} \leq |\rho_\phi| \leq e_p, \quad |r_\phi| \leq e_p$$

for every element $\phi \in Aut_p(M)$. Thus the algebraic set defined by the equalities in 14 is bounded. Note that the boundedness of the algebraic set is preserved on an open neighborhood of the point p so that there are a real number $\delta_p > 0$ and a real number $c_p \geq 1$ satisfying

$$c_p^{-1} \leq |U_\phi| \leq c_p, \quad |a_\phi| \leq c_p, \quad c_p^{-1} \leq |\rho_\phi| \leq c_p, \quad |r_\phi| \leq c_p$$

for every point $p \in B(p; \delta_p) \cap M$ and every local automorphism $\phi \in Aut_p(M)$.

Since the subset K is compact, there are finitely many points p_1, \dots, p_l such that

$$K \subset \bigcup_{k=1}^l B(p_k; \delta_{p_k}) \cap M.$$

Then we take

$$e = \max \{e_{p_k} : 1 \leq k \leq l\}.$$

This completes the proof. \square

Lemma 45. *Let M be nonspherical analytic real hypersurfaces in \mathbb{C}^{n+1} such that the isotropy subgroup $Aut_p(M)$ is compact at every point $p \in M$. Then, for each compact subset $K \subset\subset M$, there is a real number $\delta > 0$ such that each germ of a local automorphism $\phi \in Aut_p(M)$, $p \in K$, is analytically continued to the open ball $B(p; \delta)$.*

Proof. By the construction of the normalizing map μ_p , the real number δ_p depend only on the point $p \in M$. Hence there is a real number $\delta_p > 0$ for each $p \in M$ such that, for every $q \in B(p; \delta_p) \cap M$, the mapping μ_q is biholomorphic on $B(q; \delta_p)$ and the inverse μ_q^{-1} is biholomorphic on $B(0; \delta_p)$. Since K is a compact subset, there are finitely many points p_1, \dots, p_l such that

$$K \subset \bigcup_{k=1}^l B(p_k; \delta_{p_k}) \cap M.$$

Then we take

$$\delta_1 = \max \{ \delta_{p_k} : 1 \leq k \leq l \}$$

so that μ_p is biholomorphic on $B(p; \delta_1)$ and μ_p^{-1} is biholomorphic on $B(0; \delta_1)$ for every $p \in K$.

By Lemma 44, there is a real number δ_2 such that every local automorphism $\varphi \in \text{Aut}_0(\mu_p(M))$ for every $p \in K$ is biholomorphically continued to the neighborhood $B(0; \delta_2)$. Then we take

$$\delta = \min \{ \delta_1, \delta_2 \}.$$

This completes the proof. \square

Lemma 46. *Let M be a nonspherical analytic real hypersurface and $\gamma : [0, 1] \rightarrow M$ be a chain-segment. Let M' be a nonspherical analytic real hypersurface in Moser-Vitushkin normal form(cf. [Pa1]). Suppose that there is a connected open neighborhood U of the point $\gamma(0)$ and a biholomorphic mapping ϕ on U such that*

$$\phi(U \cap M) \subset M'$$

and the image $\phi(U \cap \gamma[0, 1])$ is on the straightened chain of M' . Then the mapping ϕ is analytically continued along the whole chain-segment $\gamma[0, 1]$ as a local biholomorphic mapping.

Proof. Suppose that the assertion is not true. Then there is a real number λ , $0 < \lambda \leq 1$, such that the mapping ϕ is analytically continued along all the subpath $\gamma[0, \tau]$, $\tau < \lambda$, but not the whole path $\gamma[0, \lambda]$, as a local biholomorphic mapping.

Since $\gamma[0, 1]$ is a chain-segment, there is a biholomorphic mapping φ on an open neighborhood V of the point $\gamma(\lambda)$ such that the image $\varphi(V \cap \gamma[0, 1])$ is on the straightened chain of M' . Then we take a point $p \in \varphi(V \cap \gamma[0, \lambda])$ and an open neighborhood W of the point p such that the mapping ϕ is analytically continued on W along the chain-segment $\gamma[0, 1]$ and $W \subset V$ so that

$$\phi \circ \varphi^{-1}(\varphi(W) \cap M') \subset M'$$

and the mapping $\phi \circ \varphi^{-1}$ maps the straightened chain $\varphi(W \cap \gamma[0, 1])$ of M' onto the straightened chain of M' .

Note that the composition $\psi = \phi \circ \varphi^{-1}$ is necessarily analytically continued along the whole straightened chain of M' (cf. [Pa3]). Then, by abuse of notation, the composition $\psi \circ \varphi$ is the analytic continuation of the mapping ϕ on the point $\gamma(\lambda)$ along the chain-segment $\gamma[0, 1]$. This is a contradiction. This completes the proof. \square

3.2. Analytic continuation on a real hypersurface. We defined a canonical normalization ν_p of a nondegenerate analytic real hypersurface M at a point $p \in M$ to Moser-Vitushkin normal form(cf. [Pa1]) by the same way of the canonical normalization μ_p to Moser normal form.

Lemma 47. *Let M, M' be nonspherical analytic real hypersurfaces in complex manifolds such that M' is compact and the isotropy subgroup $Aut_p(M)$ is compact at every point $p \in M$. Let $\gamma : [0, 1] \rightarrow M$ be a chain-segment and ϕ be a biholomorphic mapping on a connected open set U of the point $\gamma(0)$ such that*

$$\phi(U \cap M) \subset M'.$$

Then the mapping ϕ is analytically continued along the whole chain-segment $\gamma[0, 1]$ as a local biholomorphic mapping.

Proof. Suppose that the assertion is not true. Then, without loss of generality, we may assume that the mapping ϕ is analytically continued along all the subpath $\gamma[0, \tau], \tau < 1$, but not the whole chain-segment $\gamma[0, 1]$ as a local biholomorphic mapping. By the analytic continuation of the mapping ϕ , there is a path $\phi \circ \gamma : [0, 1) \rightarrow M'$. Then we consider the following sequences

$$\begin{aligned} p_j &\equiv \gamma\left(1 - \frac{1}{j}\right), \quad j \in \mathbb{N}^+, \\ p'_j &\equiv \phi \circ \gamma\left(1 - \frac{1}{j}\right), \quad j \in \mathbb{N}^+. \end{aligned}$$

Since M' is compact, passing to a subsequence, say m_j , there is a point $p' \in M'$ such that $p'_{m_j} \rightarrow p'$ as $j \rightarrow \infty$ so that the closure

$$\overline{\left\{p'_{m_j} \equiv \phi \circ \gamma\left(1 - \frac{1}{m_j}\right), \quad j \in \mathbb{N}^+\right\}}$$

is a compact subset in a coordinate chart of the complex manifold.

Without loss of generality, we may assume that the chain $\gamma[0, 1] \subset M$ in a coordinate chart of the complex manifold. By abuse of notation, we assume that M, M' are in \mathbb{C}^{n+1} . Let ν_p be the canonical normalization of a nondegenerate real hypersurface M at a point $p \in M$ to Moser-Vitushkin normal form.

Then the mapping ϕ yields the following germs of a biholomorphic mapping:

$$\varphi_j \equiv \nu_{p'_{m_j}} \circ \phi \circ \nu_{p_{m_j}}^{-1} : \nu_{p_{m_j}}(M) \rightarrow \nu_{p'_{m_j}}(M').$$

Since $\gamma : [0, 1] \rightarrow M$ is a chain-segment, there is a sequence of local automorphisms

$$\sigma_j \in Aut_{p_{m_j}}(M)$$

such that the mapping $\nu_{p'_{m_j}} \circ \phi \circ \sigma_j$ sends the germ of the chain γ at the point p_{m_j} onto the straightened chain of the real hypersurface $\mu_{p'_{m_j}}(M')$ in Moser-Vitushkin normal form. By Lemma 46, the composition $\psi_j = \nu_{p'_{m_j}} \circ \phi \circ \sigma_j$ is analytically continued along the whole chain-segment $\gamma[0, 1]$. Therefore, there is a real number $\delta > 0$ such that, by abuse of notation, the mapping ψ_j is biholomorphic on the open neighborhood $B(p_{m_j}; \delta)$.

By Lemma 45, the set $\left\{\nu_{p_{m_j}} \circ \sigma_j \circ \nu_{p_{m_j}}^{-1} : j \in \mathbb{N}^+\right\}$ is relatively compact.. Thus, by passing to a subsequence and shrinking $\delta > 0$, if necessary, we may assume that

the composition $\tau_j = \nu_{p_{m_j}} \circ \sigma_j \circ \nu_{p_{m_j}}^{-1}$ and its converse τ_j^{-1} are biholomorphically continued on the open neighborhood $B(0; \delta)$.

Since $p_{m_j} \rightarrow \gamma(1)$ and $p'_{m_j} \rightarrow p'$, by passing to a subsequence and shrinking $\delta > 0$, if necessary, we may assume that the canonical normalizations $\nu_{p_{m_j}}, \nu_{p'_{m_j}}$ and their inverses $\nu_{p_{m_j}}^{-1}, \nu_{p'_{m_j}}^{-1}$ are biholomorphically continued respectively on the open neighborhoods

$$B(p_{m_j}; \delta), \quad B(p'_{m_j}; \delta), \quad B(0; \delta), \quad B(0; \delta).$$

Then, by abuse of notation, the composition

$$\chi_j = \nu_{p'_{m_j}}^{-1} \circ \psi_j \circ \nu_{p_{m_j}}^{-1} \circ \tau_j^{-1} \circ \nu_{p_{m_j}}$$

is biholomorphic on the open neighborhood $B(p_{m_j}; \delta)$, if necessary, by shrinking $\delta > 0$.

Note that the mapping χ_j is a local biholomorphic continuation of the germ of the mapping ϕ at the point p_{m_j} for each $j \in \mathbb{N}^+$. Thus we take an integer K such that

$$\gamma(1) \in B\left(p_{m_K}; \frac{\delta}{2}\right)$$

so that the mapping χ_K is an analytic continuation of the mapping ϕ on the point $\gamma(1)$ along the chain-segment $\gamma[0, 1]$. This contradiction completes the proof. \square

Lemma 48. *Let M, M' be nonspherical analytic real hypersurfaces in complex manifolds such that M' is compact and the isotropy subgroup $\text{Aut}_p(M)$ is compact at every point $p \in M$. Suppose that there is a biholomorphic mapping ϕ on a connected open set U of a point $p \in M$ such that*

$$\phi(U \cap M) \subset M'.$$

Then the biholomorphic mapping ϕ is analytically continued along any path on M as a local biholomorphic mapping.

Proof. For each point $p \in M$, we make a biholomorphically equivalent deformation of the real hypersurfaces $\mu_p(M)$ in normal form continuously to a real hyperquadric by using the scaling mapping

$$\begin{cases} z^* = \lambda z \\ w^* = \lambda^2 w \end{cases}, \quad \lambda \in \mathbb{R}^+.$$

Because the chain is characterized by an order differential equation, the continuous family of chains on the real hyperquadric is continuously deformed by the parameter λ on a real hypersurface biholomorphic to M near the point p (cf. [Pa3]).

Let $\gamma : [0, 1] \rightarrow M$ be a path on M such that $\gamma(0) \in U \cap M$. Then, for each $\tau \in [0, 1]$, there is a real number $\varepsilon_\tau > 0$, a point $p_\tau \in M$ and a continuous function

$$\Gamma_\tau : [0, 1] \times ([0, 1] \cap (\tau - \varepsilon_\tau, \tau + \varepsilon_\tau)) \rightarrow M$$

such that

1. $\Gamma_\tau(\cdot, \sigma) : [0, 1] \rightarrow M$ is a chain-segment for each $\sigma \in [0, 1] \cap (\tau - \varepsilon_\tau, \tau + \varepsilon_\tau)$,
2. $\Gamma_\tau(0, \sigma) = \gamma(\sigma)$ for each $\sigma \in [0, 1] \cap (\tau - \varepsilon_\tau, \tau + \varepsilon_\tau)$,
3. $\Gamma_\tau(1, \sigma) = p_\tau$ for all $\sigma \in [0, 1] \cap (\tau - \varepsilon_\tau, \tau + \varepsilon_\tau)$.

Note that the family $\{[0, 1] \cap (\tau - \varepsilon_\tau, \tau + \varepsilon_\tau) : \tau \in [0, 1]\}$ is an open covering of the compact set $[0, 1]$. Thus there is a finite subcover

$$\{[0, 1] \cap (\tau_j - \varepsilon_{\tau_j}, \tau_j + \varepsilon_{\tau_j}) : \tau_j \in [0, 1], \quad j = 1, \dots, m\}.$$

Then, by Lemma 47, the biholomorphic mapping ϕ is analytically continued along the whole path $\gamma[0, 1]$ as a local biholomorphic mapping. This completes the proof. \square

3.3. Holomorphic mapping on the boundary.

Lemma 49. *Let Q be a real hyperquadric defined by*

$$v = \langle z, z \rangle \equiv z^1 \bar{z}^1 + \dots + z^n \bar{z}^n$$

and ϕ be a polynomial mapping as follows:

$$\phi : \begin{cases} z^* = f(z, w) \\ w^* = g(z, w) \end{cases}$$

where, for $m \geq 2$,

$$(15) \quad \begin{aligned} f(\mu z, \mu^2 w) &= \mu^m f(z, w) \\ g(\mu z, \mu^2 w) &= \mu^{2m} g(z, w). \end{aligned}$$

Suppose that

$$\phi(Q) \subset Q.$$

Then $\phi \equiv 0$.

Proof. The mapping $\phi = (f, g)$ yields the identity

$$(16) \quad \Im g(z, u + i\langle z, z \rangle) = \langle f(z, u + i\langle z, z \rangle), f(z, u + i\langle z, z \rangle) \rangle.$$

Suppose that m is even, i.e., $m = 2k \geq 2$. We may consider z, \bar{z}, u as independent variables in the identity 16. Taking $\bar{z} = 0$ in the equality 16 yields

$$g(z, u) - \bar{g}(0, u) = 2i\langle f(z, u), f(0, u) \rangle.$$

Thus we can put

$$(17) \quad g(z, u) = 2i\langle f(z, u), f(0, u) \rangle + \Re g(0, u) - i\langle f(0, u), f(0, u) \rangle.$$

Note that

$$f(0, u) = f(0, 1)u^{\frac{m}{2}}, \quad g(0, u) = g(0, 1)u^m.$$

Then the identity 16 yields

$$\begin{aligned} & 2\Re \{ \langle f(z, u + i\langle z, z \rangle), f(0, 1) \rangle (u + i\langle z, z \rangle)^{\frac{m}{2}} \} \\ & + \Re g(0, 1) \Im (u + i\langle z, z \rangle)^m \\ & - \langle f(0, 1), f(0, 1) \rangle \Re (u + i\langle z, z \rangle)^m \\ & = \langle f(z, u + i\langle z, z \rangle), f(z, u + i\langle z, z \rangle) \rangle. \end{aligned}$$

Let $p(z, \bar{z})$ be a polynomial of the variables z, \bar{z} satisfying

$$p(\mu z, \nu \bar{z}) = \mu^l \nu^m p(z, \bar{z}).$$

Then the polynomial $p(z, \bar{z})$ is said to be of type (l, m) . Collecting the terms of type $(l, 1)$, $l = 0, 1, \dots, m-1$, yields

$$miu^{-1}\langle z, z \rangle \{ \langle f(z, u), f(0, u) \rangle - \langle f(0, u), f(0, u) \rangle + \Re g(0, u) \} = 0.$$

Hence we obtain

$$\langle f(z, u), f(0, u) \rangle - \langle f(0, u), f(0, u) \rangle + \Re g(0, u) = 0,$$

so that

$$\begin{aligned} \langle f(z, u), f(0, u) \rangle &= \langle f(0, u), f(0, u) \rangle \\ \Re g(0, u) &= 0. \end{aligned}$$

Thus, from the identity 17, we obtain

$$g(z, u) = i \langle f(0, u), f(0, u) \rangle$$

by which the identity 16 yields

$$\langle f(0, 1), f(0, 1) \rangle \Re(u + i \langle z, z \rangle)^m = \langle f(z, u + i \langle z, z \rangle), f(z, u + i \langle z, z \rangle) \rangle.$$

Note that

$$\langle f(z, u + i \langle z, z \rangle), f(z, u + i \langle z, z \rangle) \rangle \geq 0,$$

but

$$\Re(u + i \langle z, z \rangle)^m = u^m - \frac{m(m-1)}{2} u^{m-2} \langle z, z \rangle^2 + \dots$$

Thus collecting terms of type (2, 2) yields

$$\begin{aligned} & -\frac{m(m-1)}{2} \langle f(0, 1), f(0, 1) \rangle u^{m-2} \langle z, z \rangle^2 \\ &= \left| \sum_{\alpha, \beta} \frac{z^\alpha \bar{z}^\beta}{2} \left(\frac{\partial^2 f}{\partial z^\alpha \partial \bar{z}^\beta} \right) (0, u) \right|^2 + \frac{mu^{-2}}{2} \langle z, z \rangle^2 \langle f(0, u), f(0, u) \rangle \\ &\geq 0. \end{aligned}$$

Since $m \geq 2$, we obtain

$$\langle f(0, 1), f(0, 1) \rangle = 0$$

which yields

$$\langle f(z, u + i \langle z, z \rangle), f(z, u + i \langle z, z \rangle) \rangle = 0,$$

i.e.,

$$f(z, w) = g(z, w) = 0.$$

Suppose that m is odd, i.e., $m = 2k + 1 \geq 3$. We may consider z, \bar{z}, u as independent variables in the identity 16. Then, by the condition 15, taking $\bar{z} = 0$ in the equality 16 yields

$$g(z, u) = \bar{g}(0, u)$$

since

$$f(0, u) = 0.$$

Thus we can put

$$g(z, u) = g(0, u), \quad g(0, 1) \in \mathbb{R}.$$

Then the identity 16 yields

$$(18) \quad g(0, 1) \Im(u + i \langle z, z \rangle)^m = \langle f(z, u + i \langle z, z \rangle), f(z, u + i \langle z, z \rangle) \rangle.$$

Note that

$$\langle f(z, u + i\langle z, z \rangle), f(z, u + i\langle z, z \rangle) \rangle \geq 0,$$

but

$$\begin{aligned} \Im(u + i\langle z, z \rangle)^m &= mu^{m-1}\langle z, z \rangle \\ &\quad - \frac{m(m-1)(m-2)}{2}u^{m-3}\langle z, z \rangle^3 + \dots. \end{aligned}$$

Thus collecting terms of type $(1, 1)$ yields

$$\begin{aligned} &mg(0, 1)u^{m-1}\langle z, z \rangle \\ &= \left| \sum_{\alpha} z^{\alpha} \left(\frac{\partial f}{\partial z^{\alpha}} \right) (0, u) \right|^2 \geq 0. \end{aligned}$$

Collecting terms of type $(3, 3)$ yields

$$\begin{aligned} &-\frac{m(m-1)(m-2)}{2}g(0, 1)u^{m-3}\langle z, z \rangle^3 \\ &= \left| \sum_{\alpha, \beta, \gamma} \frac{z^{\alpha}z^{\beta}z^{\gamma}}{6} \left(\frac{\partial^3 f}{\partial z^{\alpha}\partial z^{\beta}\partial z^{\gamma}} \right) (0, u) \right|^2 \\ &\quad + \frac{m-1}{2} \left| \sum_{\alpha} z^{\alpha} \left(\frac{\partial f}{\partial z^{\alpha}} \right) (0, u) \right|^2 u^{-2}\langle z, z \rangle^2 \\ &\geq 0. \end{aligned}$$

Since $m \geq 3$, we obtain

$$g(0, 1)\langle z, z \rangle = 0$$

by which the identity 18 yields

$$\langle f(z, u + i\langle z, z \rangle), f(z, u + i\langle z, z \rangle) \rangle = 0,$$

i.e.,

$$f(z, w) = g(z, w) = 0.$$

This completes the proof. \square

Lemma 50. *Let M, M' be strongly pseudoconvex analytic real hypersurfaces in \mathbb{C}^{n+1} . Let ϕ be a holomorphic mapping on an open neighborhood U of a point $p \in M$ such that*

$$\phi(U \cap M) \subset M'.$$

Then the mapping ϕ is either a constant mapping or a biholomorphic mapping on U , if necessary, shrinking U .

Proof. We take $q = \phi(p)$ so that

$$\varphi \equiv \mu_q \circ \phi \circ \mu_p^{-1} : \mu_p(M) \rightarrow \mu_q(M').$$

Then the mapping φ is a holomorphic mapping on an open neighborhood V of the origin satisfying

$$\varphi(\mu_p(M) \cap V) \subset \mu_q(M').$$

The mapping $\varphi = (f, g)$ in $\mathbb{C}^n \times \mathbb{C}$ is decomposed as follows:

$$f(z, w) = \sum_{k=1}^{\infty} f_k(z, w), \quad g(z, w) = \sum_{k=1}^{\infty} g_k(z, w),$$

where

$$f_m(\mu z, \mu^2 w) = \mu^m f_m(z, w), \quad g_m(\mu z, \mu^2 w) = \mu^m g_m(z, w).$$

We assume that $\mu_p(M), \mu_q(M')$ are defined respectively by the equations

$$v = F(z, \bar{z}, u), \quad v = \langle z, z \rangle + F^*(z, \bar{z}, u)$$

where

$$F(z, \bar{z}, u) = \langle z, z \rangle + O(|z|^4), \quad F^*(z, \bar{z}, u) = O(|z|^4).$$

Then we obtain the following identity near the origin

$$\begin{aligned} & \Im g(z, u + iF(z, \bar{z}, u)) \\ &= \langle f(z, u + iF(z, \bar{z}, u)), f(z, u + iF(z, \bar{z}, u)) \rangle \\ (19) \quad & + F^*(f(z, u + iF(z, \bar{z}, u)), \overline{f(z, u + iF(z, \bar{z}, u))}, \Re g(z, u + iF(z, \bar{z}, u))). \end{aligned}$$

Then, up to weight 2, we obtain

$$\begin{aligned} \Im g_1(z, 0) &= 0 \\ \Im g_2(z, u + i\langle z, z \rangle) &= \langle f_1(z, 0), f_1(z, 0) \rangle \end{aligned}$$

which yields

$$\langle f_1(z, 0), f_1(z, 0) \rangle = \langle z, z \rangle \Re g_2(0, 1)$$

and

$$\begin{aligned} g_1(z, 0) &= 0 \\ g_2(z, w) &= g_2(0, 1)w, \quad g_2(0, 1) \in \mathbb{R}. \end{aligned}$$

Note that $g_2(0, 1) \neq 0$ if and only if the mapping φ is a biholomorphic mapping at the origin.

Suppose that the assertion is not true. Then we have

$$f_1(z, 0) = g_1(z, 0) = g_2(z, w) = 0.$$

As inductive hypothesis, suppose that, for $m \geq 2$,

$$\begin{aligned} f_l(z, w) &= 0, \quad l = 1, \dots, m-1, \\ (20) \quad g_l(z, w) &= 0, \quad l = 1, \dots, 2m-2. \end{aligned}$$

By the condition

$$F(z, \bar{z}, u) = \langle z, z \rangle + O(|z|^4), \quad F^*(z, \bar{z}, u) = o(|z|^4),$$

the identity 19 yields

$$\Im g_{2m-1}(z, u + i\langle z, z \rangle) = 0$$

Here we may consider z, \bar{z}, u as independent variables so that taking $\bar{z} = 0$ yields

$$g_{2m-1}(z, u + i\langle z, z \rangle) = \overline{g_{2m-1}}(0, u - i\langle z, z \rangle) = 0.$$

Hence the hypothesis 20 necessarily comes to

$$\begin{aligned} f_l(z, w) &= 0, \quad l = 1, \dots, m-1, \\ g_l(z, w) &= 0, \quad l = 1, \dots, 2m-1. \end{aligned}$$

Then the identity 19 yields

$$\Im g_{2m}(z, u + i\langle z, z \rangle) = \langle f_m(z, u + i\langle z, z \rangle), f_m(z, u + i\langle z, z \rangle) \rangle.$$

Note that the polynomial mapping $\varphi_m \equiv (f_m, g_{2m})$, $m \geq 2$, satisfies

$$\varphi_m(Q) \subset Q.$$

By Lemma 49, $\varphi_m \equiv 0$ so that

$$\begin{aligned} f_l(z, w) &= 0, \quad l = 1, \dots, m, \\ g_l(z, w) &= 0, \quad l = 1, \dots, 2m. \end{aligned}$$

This completes the induction so that $\varphi \equiv 0$, i.e., the mapping φ is a constant mapping. This completes the proof. \square

3.4. Proper holomorphic mappings.

Lemma 51. *Let D, D' be strongly pseudoconvex bounded domains with nonspherical real analytic boundaries bD, bD' such that the boundaries bD, bD' are both simply connected. Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ such that*

$$\phi(U \cap bD) \subset bD'.$$

Then the mapping ϕ is analytically continued to a biholomorphic mapping from D onto D' .

Proof. Since bD, bD' are simply connected, by Lemma 48, the mappings ϕ, ϕ^{-1} are both analytically continued, by abuse of notation, respectively to a biholomorphic mapping

$$\phi : D \rightarrow D$$

and

$$\phi^{-1} : D' \rightarrow D.$$

Then, by the identity theorem, the mapping ϕ is biholomorphic. This completes the proof. \square

Lemma 52. *Let D, D' be strongly pseudoconvex bounded domains with nonspherical real analytic boundaries bD, bD' such the boundary bD' is simply connected and the closed set $\overline{D'}$ satisfies the fixed point property. Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ such that*

$$\phi(U \cap bD) \subset bD'.$$

Then the mapping ϕ is analytically continued to a biholomorphic mapping from D onto D' .

Proof. Since bD' is simply connected, by Lemma 48, the inverse mapping ϕ^{-1} is analytically continued to a locally biholomorphic proper mapping

$$\varphi : D' \rightarrow D.$$

Note that the mappings $\varphi : D' \rightarrow D$ and $\varphi : bD' \rightarrow bD$ are both covering maps. We claim that the covering is simple. Otherwise, there is a nontrivial deck transformation of $\overline{D'}$ yields a continuous self mapping of $\overline{D'}$ with no fixed point. This is a contradiction. Therefore, the mapping $\varphi : D' \rightarrow D$ is biholomorphic. This completes the proof. \square

Lemma 53. *Let D, D' be strongly pseudoconvex bounded domains with nonspherical real analytic boundaries bD, bD' such that the domain D and the boundary bD' are both simply connected. Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ such that*

$$\phi(U \cap bD) \subset bD'.$$

Then the mapping ϕ is analytically continued to a biholomorphic mapping from D onto D' .

Proof. Since bD' is simply connected, by Lemma 48, the inverse mapping ϕ^{-1} is analytically continued to a locally biholomorphic proper mapping

$$\varphi : D' \rightarrow D.$$

Note that the mapping $\varphi : D' \rightarrow D$ is a covering map. Since D is simply connected, the covering is simple. Therefore, the mapping $\varphi : D' \rightarrow D$ is biholomorphic. This completes the proof. \square

Theorem 54. *Let D, D' be strongly convex bounded domains with real analytic boundaries bD, bD' . Suppose that there is a biholomorphic mapping ϕ on a connected open neighborhood U of a point $p \in bD$ such that*

$$\phi(U \cap bD) \subset bD'.$$

Then the mapping ϕ is analytically continued to a biholomorphic mapping from D onto D' .

Proof. Note that a strongly convex bounded domain is homeomorphic to an open ball B^{n+1} . Suppose that the boundaries bD, bD' are spherical. Then we take a biholomorphic mapping φ on U , if necessary, shrinking U , such that

$$\varphi(U \cap bD) \subset bB^{n+1}.$$

Then, by Lemma 19, the mapping φ and the composition $\psi \equiv \varphi \circ \phi^{-1}$ are analytically continued, by abuse of notation, to biholomorphic mappings as follows:

$$\varphi : D \rightarrow B^{n+1} \quad \text{and} \quad \psi : D' \rightarrow B^{n+1}.$$

Thus the composition $\psi^{-1} \circ \varphi : D \rightarrow D'$ is a biholomorphic mapping and the analytic continuation of the mapping ϕ .

Suppose that the boundaries bD, bD' are nonspherical. Then, by Lemma 53, the mapping ϕ is analytically continued to a biholomorphic mapping from D onto D' . This completes the proof. \square

Lemma 55. *Let D, D' be strongly pseudoconvex bounded domains with real analytic boundaries bD, bD' . Suppose that there is a proper holomorphic mapping $\phi : D \rightarrow D'$. Then there is an open neighborhood U of a point $p \in bD$ such that the mapping ϕ is analytically continued on U and*

$$\phi(U \cap bD) \subset bD'.$$

Proof. We may apply the boundary regularity of Lemma 16 so that the mapping $\varphi : D \rightarrow D'$ is holomorphic on an open neighborhood of \overline{D} . This completes the proof. \square

Lemma 56. *Let $\phi : B^{n+1} \rightarrow B^{n+1}$ be a proper holomorphic mapping. Then $\phi \in \text{Aut}(B^{n+1})$.*

Proof. By Lemma 55, there is an open neighborhood U of a point $p \in bB^{n+1}$ such that ϕ is analytically continued on U and

$$\phi(U \cap bB^{n+1}) \subset bB^{n+1}.$$

By Lemma 17, $\phi \in \text{Aut}(B^{n+1})$. This completes the proof. \square

Lemma 57. *Let D, D' be strongly pseudoconvex bounded domains in \mathbb{C}^{n+1} with real analytic boundaries bD, bD' . Suppose that there is a proper holomorphic mapping $\phi : D \rightarrow D'$. Then the mapping $\phi : D \rightarrow D'$ is a locally biholomorphic mapping so that $\phi : \overline{D} \rightarrow \overline{D}'$ is a covering map.*

Proof. By Lemma 55, there is a point $p \in bD$ and an open neighborhood U of the point p such that the mapping ϕ is analytically continued to U and

$$\phi(U \cap bD) \subset bD'.$$

By Lemma 50, the mapping ϕ is biholomorphic on U , if necessary, shrinking U .

Suppose that the boundaries bD, bD' are spherical. Then, by Lemma 30, the mapping $\phi : D \rightarrow D'$ is a locally biholomorphic mapping.

Suppose that the boundary bD, bD' are nonspherical. Then, by Lemma 48, the mapping $\phi : D \rightarrow D'$ is analytically continued on an open neighborhood of the boundary bD to be locally biholomorphic. Thus the mapping ϕ is a locally biholomorphic mapping. This completes the proof. \square

Theorem 58. *Let D be a strongly pseudoconvex bounded domain with real analytic boundary bD . Suppose that there is a proper holomorphic self mapping $\phi : D \rightarrow D$. Then ϕ is a biholomorphic automorphism of D .*

Proof. By Lemma 57, the mapping $\phi : \overline{D} \rightarrow \overline{D}$ is a self covering map. We claim that $\phi : D \rightarrow D$ is a simple covering. Otherwise, there would be a integer $m > 1$ such that, for every $p \in \overline{D}$, m is the order of the set

$$\{q \in \overline{D} : \phi(q) = p\}.$$

Then we define the k times composition ϕ^k of the mapping ϕ as follows

$$\phi^k \equiv \underbrace{\phi \circ \cdots \circ \phi}_k : \overline{D} \rightarrow \overline{D}.$$

Note that the inverse image of each point $p \in \overline{D}$ under the mapping $\phi^k : \overline{D} \rightarrow \overline{D}$, $k \in \mathbb{N}^+$, is a set of order m^k .

We claim that, for a given real number $\delta > 0$, there is a point $q \in bD$ and a compact subset $K \subset\subset D$ and a subsequence ϕ^{m_k} such that

$$\phi^{-m_k}(B(q; \delta) \cap D) \cap K \neq \emptyset \quad \text{for all } k \in \mathbb{N}^+.$$

Otherwise, for every compact subset $K \subset\subset D$, there is an integer l such that

$$\phi^{-k}(D \setminus K) \subset D \setminus K \quad \text{for all } k \geq l.$$

Since $\phi^k : D \rightarrow D$ is a finite covering map, we have

$$D = \phi^{-k}(K \cup D \setminus K) = \phi^{-k}(K) \cup \phi^{-k}(D \setminus K)$$

so that

$$K \subset \phi^{-k}(K) \quad \text{for all } k \geq l.$$

Note that the inverse image of $\phi^{-k}(K)$ is a union of m^k disconnected compact subsets. We may assume that K is connected so that K is in a compact subset of the union $\phi^{-k}(K)$. This is impossible. Thus, with such a point $q \in bD$, we take an accumulation point $q' \in D'$ of the set

$$\lim_{k \rightarrow \infty} \phi^{-m_k}(\{q\}) = \lim_{k \rightarrow \infty} \{p \in bD : \phi^{m_k}(p) = q\}.$$

Suppose that bD is spherical. Then there are open neighborhoods U, U' respectively of q, q' and biholomorphic mappings ψ, ψ' respectively on U, U' such that

$$\begin{aligned} \psi(U \cap bD) &\subset bB^{n+1} \\ \psi'(U' \cap bD) &\subset bB^{n+1}. \end{aligned}$$

By Lemma 17, the compositions

$$\varphi_k \equiv \psi' \circ \phi^{-k} \circ \psi^{-1} : \psi(U \cap D) \rightarrow \psi'(U' \cap D)$$

is analytically continued to, by abuse of notation, automorphisms $\varphi_k \in \text{Aut}(B^{n+1})$. By the construction, a subsequence φ_{m_k} must converges to the point $\psi'(q')$ uniformly on every compact subset of B^{n+1} . Thus there is a sequence of real numbers $\delta_k \searrow 0$ such that

$$\phi^{m_k} : B(q'; \delta_k) \cap D \rightarrow U \cap D$$

and

$$\phi^{m_k} = \psi^{-1} \circ \varphi_{m_k}^{-1} \circ \psi' \quad \text{on } B(q'; \delta_k) \cap D.$$

Then we take a point $p \in U \cap D$ such that there is a sequence q_k satisfying

$$q_k \in \phi^{-m_k}(\{p\}) \cap B(q'; \delta_k)$$

and, for a compact subset $K \subset\subset D$, there is a sequence p_k satisfying

$$p_k \in \phi^{-m_k}(\{p\}) \cap K.$$

Therefore, there is a sequence of deck transformations $\phi_k \in \text{Aut}(D)$ of the covering map $\phi^{m_k} : D \rightarrow D$ such that

$$\phi_k(p_k) = q_k \rightarrow q' \in bD.$$

Since $p_k \in K$, by Lemma 15, there is a biholomorphic mapping

$$\sigma : D \rightarrow B^{n+1}.$$

Then the composition

$$\iota \equiv \sigma \circ \phi \circ \sigma^{-1} : B^{n+1} \rightarrow B^{n+1}$$

would be a proper self mapping, but not an automorphism of the unit ball B^{n+1} . This is a contradiction to Lemma 56 that every proper self mapping of the unit ball B^{n+1} is an automorphism of the unit ball B^{n+1} .

Suppose that bD is nonspherical. We take a sequence $p_k \in bD$ such that

$$p_k \in \phi^{-k}(\{q\}) \subset bD$$

and

$$|p_k - q'| = \min \{|p - q'| : p \in \phi^{-k}(\{q\})\}.$$

Let μ_{p_k} be the canonical normalizing mapping at the point $p_k \in bD$. Since $p_k \rightarrow q'$, there is an open neighborhood W of the point q' such that the mapping μ_{p_k} is analytically continued on W . Then we define a function $\varepsilon_k(p)$ for a sufficiently large k and a point $p \in W \cap bD$ such that

$$\varepsilon_k(p) \equiv \sum_{j=1}^n |z_j \circ \mu_{p_k}(p)|^2 + |w \circ \mu_{p_k}(p)|$$

where z_j , $j = 1, \dots, n$, w are the coordinate functions of \mathbb{C}^{n+1} such that z_j , $j = 1, \dots, n$, are for the complex tangent hyperplane and w are for the complex line normal to the complex tangent hyperplane of $\mu_{p_k}(W \cap bD)$ at the origin. Then we take a sequence q_k such that

$$q_k \in \phi^{-k}(\{q\}) \subset bD$$

and

$$\varepsilon_k(q_k) = \min \{\varepsilon_k(p) : p \in \phi^{-k}(\{q\})\}.$$

Let π_k be a complex line containing p_k and q_k . Then we take a subsequence π_{m_k} so that π_{m_k} converges to a complex line $\pi_{q'} \subset T_{q'}\mathbb{C}^{n+1}$. In other words, the a subsequence q_{m_k} converges to the point q' to a direction. Then we obtain

$$\varphi_k \equiv \mu_{p_k} \circ \phi^{-k} \circ \mu_q^{-1} : \mu_q(bD) \rightarrow \mu_{p_k}(bD).$$

Then we define a biholomorphic mapping

$$\sigma_k : \begin{cases} z^* = \sqrt{\varepsilon_{m_k}} z \\ w^* = \varepsilon_{m_k} w \end{cases}$$

where

$$\varepsilon_{m_k} = \varepsilon_{m_k}(q_{m_k}).$$

Then we take the composition

$$\kappa_k \equiv \sigma_k^{-1} \circ \varphi_{m_k} : \mu_q(bD) \rightarrow \sigma_k^{-1} \circ \mu_{p_{m_k}}(bD).$$

Note that there is a real number $\delta > 0$ such that the germs of real hypersurfaces $\mu_q(bD)$ and $\sigma_k^{-1} \circ \mu_{p_{m_k}}(bD)$ are analytically continued to the open neighborhood $B(0; \delta)$. Since the boundary bD is nonspherical, by Lemma 45, the mapping κ_k is biholomorphic on $B(0; \delta)$, if necessary, shrinking $\delta > 0$. Further, by the construction, the limit of the sequence κ_k cannot be a constant mapping on $B(0; \delta)$ so that, by Theorem 50, the limit of the sequence κ_k would be biholomorphic on $B(0; \delta)$.

By the way, the sequence of real hypersurfaces $\sigma_k^{-1} \circ \mu_{p_{m_k}}(bD)$ converges to a real hyperquadric uniformly on an open neighborhood of the origin. Therefore, the germ of the boundary bD at the point q' is spherical so that the boundary bD is spherical(cf. [Pa3]). This is a contradiction to the fact that the boundary bD is nonspherical. This completes the proof. \square

3.5. Locally realizable CR manifolds. Let M be a CR manifold of CR dimension n and CR codimension 1 with a CR structure (D, I) where D is $2n$ dimensional smooth subbundle of the tangent bundle TM and I is an automorphism on D such that

$$I^2V = -V \quad \text{for } V \in \Gamma D.$$

For each point $p \in M$, there is a local coordinate chart (U, φ) such that

$$\varphi(U) \subset \mathbb{R}^{2n+1}.$$

Then M shall be called locally realizable CR manifold if there is an open neighborhood U of each point $p \in M$ and CR functions f_1, \dots, f_{n+1} on $\varphi(U)$ satisfying

$$df_1 \wedge \dots \wedge df_{n+1} \neq 0.$$

Let $z_j, j = 1, \dots, n+1$, be the coordinate functions of \mathbb{C}^{n+1} . Then we obtain a local embedding σ of $U \subset M$ into \mathbb{C}^{n+1} such that

$$f_j \equiv z_j \circ \sigma \circ \varphi^{-1}.$$

The CR manifold M shall be called a locally analytically realizable CR manifold when $\sigma(U)$ is real analytic by a local embedding σ on an open neighborhood U of each point $p \in M$. Note that M is either spherical or nonspherical(cf. [Pa3]).

Lemma 59. *Let M be a connected locally analytically realizable CR manifold. Suppose that there is a nontrivial CR mapping φ on an open neighborhood U of a point $p \in M$ such that*

$$\varphi(U) \subset bB^{n+1}.$$

Then the mapping φ is CR continued along any path on M as a locally CR diffeomorphic mapping.

Proof. Since M is connected, M is necessarily spherical(cf. [Pa3]). Suppose that the assertion is not true. Then there is a path $\gamma : [0, 1] \rightarrow M$ with $\gamma(0) = p$ such that the mapping φ is CR continued along all subpath $\gamma[0, \tau]$ with $\tau < 1$, but not the whole path $\gamma[0, 1]$. Then we take a CR embedding $\sigma(V) \subset \mathbb{C}^{n+1}$ of an open neighborhood V of the point $\gamma(1)$ such that $\sigma(V)$ is a spherical analytic real hypersurface and

$$\varphi \circ \sigma^{-1} : \sigma(V) \rightarrow bB^{n+1}$$

is a locally CR diffeomorphism. Without loss of generality, we may assume that $\gamma[0, 1] \subset V$. Hence there is an open neighborhood W of the point $\sigma(\gamma(0))$ and a biholomorphic mapping ϕ on W such that

$$\phi = \varphi \circ \sigma^{-1} \quad \text{on } \sigma(V) \cap W.$$

Then the mapping ϕ is analytically continued along the whole path $\sigma(\gamma[0, 1])$. From, by abuse of notation, the mapping ϕ at an open neighborhood W' of the point $\sigma(\gamma(1))$ and a CR embedding σ of an open neighborhood V' of the point $\gamma(1)$, we obtain the CR mapping

$$\phi \circ \sigma : \sigma^{-1}(W' \cap \sigma(V')) \rightarrow bB^{n+1}$$

which is a CR continuation of the CR mapping φ . This completes the proof. \square

Theorem 60. *Let M be a connected locally analytically realizable CR manifold. Suppose that M is compact and there is a nontrivial CR mapping φ on an open neighborhood U of a point $p \in M$ such that*

$$\varphi(U) \subset bB^{n+1}.$$

Then there is a finite subset $L \subset bB^{n+1}$ such that the inverse CR mapping φ^{-1} is CR continued along any path on $bB^{n+1} \setminus L$ as a locally CR diffeomorphic mapping.

Proof. Since M is connected, M is necessarily spherical (cf. [Pa3]). Let $q_j \in bB^{n+1}$ be a sequence converging to a point $q \in bB^{n+1}$ and ϕ_j be a sequence of the CR continuation of the inverse mapping φ^{-1} at the point q_j . We set

$$q'_j = \phi_j(q_j) \in M.$$

Since M is compact, there is a subsequence q'_{m_j} and a point $q' \in M$ such that

$$q'_{m_j} \rightarrow q'.$$

Then we take a CR embedding σ of an open neighborhood V of the point $q' \in M$ such that $\sigma(V) \subset \mathbb{C}^{n+1}$ is a spherical analytic real hypersurface. Then we apply the same argument as in the previous sections so that the singular locus L is a finite subset of bB^{n+1} and the inverse CR mapping φ^{-1} is CR continued along any path on $bB^{n+1} \setminus L$. This completes the proof. \square

Lemma 61. *Let M, M' be connected locally analytically realizable CR manifolds with positive definite Levi form. Suppose that M, M' are nonspherical and M' is compact, and there is a nontrivial CR mapping φ on an open neighborhood U of a point $p \in M$ such that*

$$\varphi(U) \subset M'.$$

Then the mapping φ is CR continued along any path on M as a locally CR diffeomorphic mapping.

Proof. Since M, M' are locally analytically realizable and the Levi forms of M, M' are positive definite, the isotropy subgroups $Aut_p(M), Aut_{p'}(M')$ are compact for every point $p \in M, p' \in M'$.

Let $q_j \in M$ be a sequence converging to a point $q \in M$ and φ_j be a sequence of the CR continuation of the mapping φ at the point q_j . We set

$$q'_j = \varphi_j(q_j) \in M'.$$

Since M' is compact, there is a subsequence q'_{m_j} and a point $q' \in M'$ such that

$$q'_{m_j} \rightarrow q'.$$

Then we take CR embeddings σ, σ' respectively of open neighborhoods V, V' respectively of the points $q \in M, q' \in M'$ such that $\sigma(V), \sigma'(V') \subset \mathbb{C}^{n+1}$ are nonspherical analytic real hypersurface. Then we apply the same argument as in the previous subsection. This completes the proof. \square

Theorem 62. *Let M, M' be connected locally analytically realizable CR manifolds with positive definite Levi form. Suppose that M, M' are compact and nonspherical, and there is a nontrivial CR mapping φ on an open neighborhood U of a point $p \in M$ such that*

$$\varphi(U) \subset M'.$$

Then the maximal CR extension of the mapping φ is a CR equivalence between the natural universal covering spaces of M, M' to be the pointed path spaces respectively of M, M' mod homotopic relation.

Proof. By Lemma 61, the mapping φ is CR continued along any path on M as a locally CR diffeomorphic mapping. Note that M is compact and

$$\varphi^{-1}(\varphi(U)) \subset M$$

so that we apply Lemma 61 to the inverse mapping φ^{-1} . Thus the inverse mapping φ^{-1} is CR continued along any path on M' as a locally CR diffeomorphic mapping. Thus the CR continuation of the mapping ϕ induces a CR equivalence between the natural universal coverings of M, M' , which are the path spaces mod homotopic relation respectively over M, M' with the natural CR structure. This completes the proof. \square
