

Higher homotopy commutativity and cohomology of finite H -spaces

YUTAKA HEMMI
YUSUKE KAWAMOTO

We study connected mod p finite A_p -spaces admitting AC_n -space structures with $n < p$ for an odd prime p . Our result shows that if $n > (p - 1)/2$, then the mod p Steenrod algebra acts on the mod p cohomology of such a space in a systematic way. Moreover, we consider A_p -spaces which are mod p homotopy equivalent to product spaces of odd dimensional spheres. Then we determine the largest integer n for which such a space admits an AC_n -space structure compatible with the A_p -space structure.

[55P45](#), [57T25](#); [55P48](#), [55S05](#)

1 Introduction

In this paper, we assume that p is a fixed odd prime and that all spaces are localized at p in the sense of Bousfield–Kan [2].

In the paper [10], we introduced the concept of AC_n -space which is an A_n -space whose multiplication satisfies the higher homotopy commutativity of the n -th order. Then we showed that a mod p finite AC_n -space with $n \geq p$ has the homotopy type of a torus. Here by being mod p finite, we mean that the mod p cohomology of the space is finite dimensional. To prove it, we first studied the action of the Steenrod operations on the mod p cohomology of such a space. Then we showed that the possible cohomology generators are concentrated in dimension 1.

In the above argument, the condition $n \geq p$ is essential. In fact, any odd dimensional sphere admits an AC_{p-1} -space structure by [10, Proposition 3.8]. This implies that for any given exterior algebra, we can construct a mod p finite AC_{p-1} -space such that the mod p cohomology of it is isomorphic to the algebra.

On the other hand, if the A_{p-1} -space structure of the AC_{p-1} -space is extendable to an A_p -space structure, then the situation is different. For example, it is known that an

odd dimensional sphere with an A_p -space structure does not admit an AC_{p-1} -space structure except for S^1 . In fact, an odd dimensional sphere S^{2m-1} admits an A_p -space structure if and only if $m|(p-1)$, and then it admits an AC_n -space structure compatible with the A_p -space structure if and only if $nm \leq p$ by [6, Theorem 2.4]. In particular, if $p = 3$, then mod 3 finite A_3 -space with AC_2 -space structure means mod 3 finite homotopy associative and homotopy commutative H -space. Then by Lin [21], such a space has the homotopy type of a product space of S^1 s and $Sp(2)$ s.

In this paper, we study mod p finite A_p -spaces with AC_n -space structures for $n < p$. First we consider the case of $n > (p-1)/2$. In this case, we show the following fact on the action of the Steenrod operations:

Theorem A *Let p be an odd prime. If X is a connected mod p finite A_p -space admitting an AC_n -space structure with $n > (p-1)/2$, then we have the following:*

(1) *If $a \geq 0$, $b > 0$ and $0 < c < p$, then*

$$QH^{2p^a(pb+c)-1}(X; \mathbb{Z}/p) = \mathcal{P}^{p^at}QH^{2p^a(p(b-t)+c+t)-1}(X; \mathbb{Z}/p)$$

for $1 \leq t \leq \min\{b, p-c\}$ and

$$\mathcal{P}^{p^at}QH^{2p^a(pb+c)-1}(X; \mathbb{Z}/p) = 0$$

for $c \leq t < p$.

(2) *If $a \geq 0$ and $0 < c < p$, then*

$$\mathcal{P}^{p^at}: QH^{2p^ac-1}(X; \mathbb{Z}/p) \longrightarrow QH^{2p^a(tp+c-t)-1}(X; \mathbb{Z}/p)$$

is an isomorphism for $1 \leq t < c$.

In the above theorem, the assumption $n > (p-1)/2$ is necessary. In fact, (2) is not satisfied for the Lie group S^3 although S^3 admits an $AC_{(p-1)/2}$ -space structure for any odd prime p as is proved in [6, Theorem 2.4].

Theorem A (1) has been already proved for a special case or under additional hypotheses: for $p = 3$ by Hemmi [7, Theorem 1.1] and for $p \geq 5$ by Lin [19, Theorem B] under the hypotheses that the space admits an AC_{p-1} -space structure and the mod p cohomology is A_p -primitively generated (see Hemmi [8] and Lin [19]).

In the above theorem, we assume that the prime p is odd. However, if we consider the case $p = 2$, then the condition $p > n > (p-1)/2$ is equivalent to $n = 1$, which means that the space is just an H -space. Thus Theorem A can be considered as the

odd prime version of Thomas [26, Theorem 1.1] or Lin [18, Theorem 1]. (Note that in their theorems they assumed that the mod 2 cohomology of the space is primitively generated, while we do not need such an assumption.)

By using Theorem A, we show the following result:

Theorem B *Let p be an odd prime. If X is a connected mod p finite A_p -space admitting an AC_n -space structure with $n > (p - 1)/2$ and the Steenrod operations \mathcal{P}^j act on $QH^*(X; \mathbb{Z}/p)$ trivially for $j \geq 1$, then X is mod p homotopy equivalent to a torus.*

Next we consider the case of $n \leq (p - 1)/2$. This includes the case $n = 1$, which means that the space is just a mod p finite A_p -space. For the cohomology of mod p finite A_p -spaces, we can show similar facts to Theorem A. For example, the results by Thomas [26, Theorem 1.1] and Lin [18, Theorem 1] mentioned above is for $p = 2$, and for odd prime p , many results are known (cf. [1], [5], [20]).

However, for odd primes in particular, those results have some ambiguities. In fact, there are many A_p -spaces with AC_n -space structures for some $n \leq (p - 1)/2$ such that the Steenrod operations act on the cohomology trivially. In the next theorem, we determine n for which a product space of odd dimensional spheres to be an A_p -space with an AC_n -space structure.

Theorem C *Let X be a connected A_p -space mod p homotopy equivalent to a product space of odd dimensional spheres $S^{2m_1-1} \times \cdots \times S^{2m_l-1}$ with $1 \leq m_1 \leq \cdots \leq m_l$, where p is an odd prime. Then X admits an AC_n -space structure if and only if $nm_l \leq p$.*

By the results of Clark–Ewing [4] and Kumpel [17], there are many spaces satisfying the assumption of Theorem C. Moreover, we note that the above result generalizes [6, Theorem 2.4].

This paper is organized as follows: In Section 2, we first recall the modified projective space $\mathcal{M}(X)$ of a finite A_p -space constructed by Hemmi [8]. Based on the mod p cohomology of $\mathcal{M}(X)$, we construct an algebra $A^*(X)$ over the mod p Steenrod algebra which is a truncated polynomial algebra at height $p + 1$ (Theorem 2.1). Next we introduce the concept of \mathcal{D}_n -algebra and show that if X is an A_p -space with an AC_n -space structure, then $A^*(X)$ is a \mathcal{D}_n -algebra (Theorem 2.6). Finally we prove the theorems in Section 3 by studying the action of the Steenrod algebra on \mathcal{D}_n -algebras algebraically (Proposition 3.1 and Proposition 3.2).

This paper is dedicated to Professor Goro Nishida on his 60th birthday. The authors appreciate the referee for many useful comments.

2 Modified projective spaces

Stasheff [25] introduced the concept of A_n -space which is an H -space with multiplication satisfying higher homotopy associativity of the n -th order. Let X be a space and $n \geq 2$. An A_n -form on X is a family of maps $\{M_i: K_i \times X^i \rightarrow X\}_{2 \leq i \leq n}$ with the conditions of [25, I, Theorem 5], where $\{K_i\}_{i \geq 2}$ are polytopes called the associahedra. A space X having an A_n -form is called an A_n -space. From the definition, an A_2 -space and an A_3 -space are the same as an H -space and a homotopy associative H -space, respectively. Moreover, it is known that an A_∞ -space has the homotopy type of a loop space.

Let X be an A_n -space. Then by Stasheff [25, I, Theorem 5], there is a family of spaces $\{P_i(X)\}_{1 \leq i \leq n}$ called the projective spaces associated to the A_n -form on X . From the construction of $P_i(X)$, we have the inclusion $\iota_{i-1}: P_{i-1}(X) \rightarrow P_i(X)$ for $2 \leq i \leq n$ and the projection $\rho_i: P_i(X) \rightarrow P_i(X)/P_{i-1}(X) \simeq (\Sigma X)^{(i)}$ for $1 \leq i \leq n$, where $Z^{(i)}$ denotes the i -fold smash product of a space Z for $i \geq 1$.

For the rest of this section, we assume that X is a connected A_p -space whose mod p cohomology $H^*(X; \mathbb{Z}/p)$ is an exterior algebra

$$(2-1) \quad H^*(X; \mathbb{Z}/p) \cong \Lambda(x_1, \dots, x_l) \quad \text{with } \deg x_i = 2m_i - 1$$

for $1 \leq i \leq l$, where $1 \leq m_1 \leq \dots \leq m_l$.

Iwase [12] studied the mod p cohomology of the projective space $P_n(X)$ for $1 \leq n \leq p$. If $1 \leq n \leq p-1$, then there is an ideal $S_n \subset H^*(P_n(X); \mathbb{Z}/p)$ closed under the action of the mod p Steenrod algebra \mathcal{A}_p^* such that

$$(2-2) \quad H^*(P_n(X); \mathbb{Z}/p) \cong T_n \oplus S_n \quad \text{with } T_n = T^{[n+1]}[y_1, \dots, y_l],$$

where $T^{[n+1]}[y_1, \dots, y_l]$ denotes the truncated polynomial algebra at height $n+1$ generated by $y_i \in H^{2m_i}(P_n(X); \mathbb{Z}/p)$ with $\iota_1^* \dots \iota_{n-1}^*(y_i) = \sigma(x_i)$ for $1 \leq i \leq l$. He also proved a similar result for the mod p cohomology of $P_p(X)$ under an additional assumption that the generators $\{x_i\}_{1 \leq i \leq l}$ are A_p -primitive (see Hemmi [8] and Iwase [12]).

Hemmi [8] modified the construction of the projective space $P_p(X)$ to get the algebra $T^{[p+1]}[y_1, \dots, y_l]$ also for $n = p$ without the assumption of the A_p -primitivity of the generators. Then he proved the following result:

Theorem 2.1 (Hemmi [8, Theorem 1.1]) *Let X be a simply connected A_p -space whose mod p cohomology $H^*(X; \mathbb{Z}/p)$ is an exterior algebra in (2–1), where p is an odd prime. Then we have a space $\mathcal{M}(X)$ and a map $\epsilon: \Sigma X \rightarrow \mathcal{M}(X)$ with the following properties:*

(1) *There is a subalgebra $R^*(X)$ of $H^*(\mathcal{M}(X); \mathbb{Z}/p)$ with*

$$R^*(X) \cong T^{[p+1]}[y_1, \dots, y_l] \oplus M,$$

where $y_i \in H^{2m_i}(\mathcal{M}(X); \mathbb{Z}/p)$ are classes with $\epsilon^(y_i) = \sigma(x_i)$ for $1 \leq i \leq l$ and $M \subset H^*(\mathcal{M}(X); \mathbb{Z}/p)$ is an ideal with $\epsilon^*(M) = 0$ and $M \cdot H^*(\mathcal{M}(X); \mathbb{Z}/p) = 0$.*

(2) *$R^*(X)$ and M are closed under the action of \mathcal{A}_p^* , and so*

$$(2-3) \quad A^*(X) = R^*(X)/M \cong T^{[p+1]}[y_1, \dots, y_l]$$

is an unstable \mathcal{A}_p^ -algebra.*

(3) *ϵ^* induces an \mathcal{A}_p^* -module isomorphism:*

$$QA^*(X) \longrightarrow QH^{*-1}(X; \mathbb{Z}/p).$$

Next we recall the higher homotopy commutativity of H -spaces.

Kapranov [16] and Reiner–Ziegler [23] constructed special polytopes $\{\Gamma_n\}_{n \geq 1}$ called the permuto–associahedra. Let $n \geq 1$. A partition of the sequence $\mathbf{n} = (1, \dots, n)$ of type (t_1, \dots, t_m) is an ordered sequence $(\alpha_1, \dots, \alpha_m)$ consisting of disjoint subsequences α_i of \mathbf{n} of length t_i with $\alpha_1 \cup \dots \cup \alpha_m = \mathbf{n}$ (see Hemmi–Kawamoto [10] and Ziegler [28] for the full details of the partitions). By Ziegler [28, Definition 9.13, Example 9.14], the permuto–associahedron Γ_n is an $(n - 1)$ -dimensional polytope whose facets (codimension one faces) are represented by the partitions of \mathbf{n} into at least two parts. Let $\Gamma(\alpha_1, \dots, \alpha_m)$ denote the facet of Γ_n corresponding to a partition $(\alpha_1, \dots, \alpha_m)$. Then the boundary of Γ_n is given by

$$(2-4) \quad \partial\Gamma_n = \bigcup_{(\alpha_1, \dots, \alpha_m)} \Gamma(\alpha_1, \dots, \alpha_m)$$

for all partitions $(\alpha_1, \dots, \alpha_m)$ of \mathbf{n} with $m \geq 2$. If $(\alpha_1, \dots, \alpha_m)$ is of type (t_1, \dots, t_m) , then the facet $\Gamma(\alpha_1, \dots, \alpha_m)$ is homeomorphic to the product $K_m \times \Gamma_{t_1} \times \dots \times \Gamma_{t_m}$

Figure 1: Permuto-associahedra Γ_2 and Γ_3

by the face operator $\epsilon^{(\alpha_1, \dots, \alpha_m)}: K_m \times \Gamma_{t_1} \times \dots \times \Gamma_{t_m} \rightarrow \Gamma(\alpha_1, \dots, \alpha_m)$ with the relations of [10, Proposition 2.1]. Moreover, there is a family of degeneracy operators $\{\delta_j: \Gamma_i \rightarrow \Gamma_{i-1}\}_{1 \leq j \leq i}$ with the conditions of [10, Proposition 2.3].

By using the permuto-associahedra, Hemmi and Kawamoto [10] introduced the concept of AC_n -form on A_n -spaces.

Let X be an A_n -space whose A_n -form is given by $\{M_i\}_{2 \leq i \leq n}$. An AC_n -form on X is a family of maps $\{Q_i: \Gamma_i \times X^i \rightarrow X\}_{1 \leq i \leq n}$ with the following conditions:

$$(2-5) \quad Q_1(*, x) = x.$$

$$(2-6) \quad Q_i(\epsilon^{(\alpha_1, \dots, \alpha_m)}(\sigma, \tau_1, \dots, \tau_m), x_1, \dots, x_i) \\ = M_m(\sigma, Q_{t_1}(\tau_1, x_{\alpha_1(1)}, \dots, x_{\alpha_1(t_1)}), \dots, Q_{t_m}(\tau_m, x_{\alpha_m(1)}, \dots, x_{\alpha_m(t_m)}))$$

for a partition $(\alpha_1, \dots, \alpha_m)$ of \mathbf{i} of type (t_1, \dots, t_m) .

$$(2-7) \quad Q_i(\tau, x_1, \dots, x_{j-1}, *, x_{j+1}, \dots, x_i) = Q_{i-1}(\delta_j(\tau), x_1, \dots, x_{j-1}, x_{j+1}, \dots, x_i)$$

for $1 \leq j \leq i$.

By [10, Example 3.2 (1)], an AC_2 -form on an A_2 -space is the same as a homotopy commutative H -space structure since $Q_2: \Gamma_2 \times X^2 \rightarrow X$ gives a commuting homotopy between xy and yx for $x, y \in X$ (see Figure 2). Let us explain an AC_3 -form on an A_3 -space. Assume that X is an A_3 -space admitting an AC_2 -form. Then by using the associating homotopy $M_3: K_3 \times X^3 \rightarrow X$ and the commuting homotopy $Q_2: \Gamma_2 \times X^2 \rightarrow X$, we can define a map $\tilde{Q}_3: \partial\Gamma_3 \times X^3 \rightarrow X$ which is illustrated

by the right dodecagon in Figure 2. For example, the uppermost edge represents the commuting homotopy between xy and yx , and thus it is given by $Q_2(t, x, y)z$. On the other hand, the next right edge is the associating homotopy between $(xy)z$ and $x(yz)$ which is given by $M_3(t, x, y, z)$. Then X admits an AC_3 -form if and only if \tilde{Q}_3 is extended to a map $Q_3: \Gamma_3 \times X^3 \rightarrow X$. Moreover, if X is an H -space, then by [10,

Figure 2: $Q_2(t, x, y)$ and $Q_3(\tau, x, y, z)$

Example 3.2 (3)], the multiplication of the loop space ΩX on X admits an AC_∞ -form.

Hemmi [6] considered another concept of higher homotopy commutativity of H -spaces. Let X be an A_n -space with the projective spaces $\{P_i(X)\}_{1 \leq i \leq n}$. Let $J_i(\Sigma X)$ be the i -th stage of the James reduced product space of ΣX and $\pi_i: J_i(\Sigma X) \rightarrow (\Sigma X)^{(i)}$ be the obvious projection for $1 \leq i \leq n$. A quasi C_n -form on X is a family of maps $\{\psi_i: J_i(\Sigma X) \rightarrow P_i(X)\}_{1 \leq i \leq n}$ with the following conditions:

$$(2-8) \quad \psi_1 = 1_{\Sigma X}: \Sigma X \longrightarrow \Sigma X.$$

$$(2-9) \quad \psi_i|_{J_{i-1}(\Sigma X)} = \iota_{i-1}\psi_{i-1} \quad \text{for } 2 \leq i \leq n.$$

$$(2-10) \quad \rho_i \psi_i \simeq \left(\sum_{\sigma \in \Sigma_i} \sigma \right) \pi_i \quad \text{for } 1 \leq i \leq n,$$

where the symmetric group Σ_i acts on $(\Sigma X)^{(i)}$ by the permutation of the coordinates and the summation on the right hand side is given by using the obvious co- H -structure on $(\Sigma X)^{(i)}$ for $1 \leq i \leq n$.

Hemmi and Kawamoto [10] proved the following result:

Theorem 2.2 (Hemmi–Kawamoto [10, Theorem A]) *Let X be an A_n -space for $n \geq 2$. Then we have the following:*

- (1) If X admits an AC_n -form, then X admits a quasi C_n -form.
- (2) If X is an A_{n+1} -space admitting a quasi C_n -form, then X admits an AC_n -form.

Remark 2.3 In the proof of [Theorem 2.2](#) (2), we do not need the condition (2-10). In fact, the proof of [Theorem 2.2](#) (2) shows that if X is an A_{n+1} -space and there is a family of maps $\{\psi_i\}_{1 \leq i \leq n}$ with the conditions (2-8)–(2-9), then there is a family of maps $\{Q_i\}_{1 \leq i \leq n}$ with the conditions (2-5)–(2-7).

Now we give the definition of \mathcal{D}_n -algebra:

Definition 2.4 Assume that A^* is an unstable \mathcal{A}_p^* -algebra for a prime p . Let $n \geq 1$. Then A^* is called a \mathcal{D}_n -algebra if for any $\alpha_i \in A^*$ and $\theta_i \in \mathcal{A}_p^*$ for $1 \leq i \leq q$ with

$$(2-11) \quad \sum_{i=1}^q \theta_i(\alpha_i) \in DA^*,$$

there are decomposable classes $\nu_i \in DA^*$ for $1 \leq i \leq q$ with

$$(2-12) \quad \sum_{i=1}^q \theta_i(\alpha_i - \nu_i) \in D^{n+1}A^*,$$

where DA^* and D^tA^* denote the decomposable module and the t -fold decomposable module of A^* for $t > 1$, respectively.

Remark 2.5 It is clear from [Definition 2.4](#) that any unstable \mathcal{A}_p^* -algebra is a \mathcal{D}_1 -algebra. On the other hand, for an A_p -space X which satisfies the assumption of [Theorem 2.1](#) with $l \geq 1$, the unstable \mathcal{A}_p^* -algebra $A^*(X)$ given in (2-3) cannot be a \mathcal{D}_p -algebra since $\mathcal{P}^m(\alpha) = \alpha^p \neq 0$ for $\alpha \in QA^{2m}(X)$ from the unstable condition of \mathcal{A}_p^* and $D^{p+1}A^*(X) = 0$ in (2-12).

To prove [Theorem A](#) and [Theorem B](#), we need the following theorem:

Theorem 2.6 Let p be an odd prime and $1 \leq n \leq p-1$. Assume that X is a simply connected A_p -space whose mod p cohomology $H^*(X; \mathbb{Z}/p)$ is an exterior algebra in (2-1). If the multiplication of X admits a quasi C_n -form, then $A^*(X)$ is a \mathcal{D}_n -algebra.

We need the following result which is a generalization of Hemmi [6]:

Lemma 2.7 Assume that X satisfies the same assumptions as [Theorem 2.6](#). If $\alpha_i \in H^*(P_n(X); \mathbb{Z}/p)$ and $\theta_i \in \mathcal{A}_p^*$ for $1 \leq i \leq q$ satisfy

$$\sum_{i=1}^q \theta_i(\alpha_i) = a + b \quad \text{with } a \in DH^*(P_n(X); \mathbb{Z}/p) \text{ and } b \in S_n,$$

then there are decomposable classes $\nu_i \in DH^*(P_n(X); \mathbb{Z}/p)$ for $1 \leq i \leq q$ with

$$\sum_{i=1}^q \theta_i(\alpha_i - \nu_i) = b.$$

Proof We give an outline of the proof since the argument is similar to Hemmi [6, Lemma 4.8]. It is clear for $n = 1$. If the result is proved for $n - 1$, then by the same reason as [6, Lemma 4.8], we can assume $a \in D^n H^*(P_n(X); \mathbb{Z}/p)$.

Put $\mathcal{U}_n = \tilde{H}^*((\Sigma X)^{[n]}; \mathbb{Z}/p)$, $\mathcal{V}_n = QH^*(X; \mathbb{Z}/p)^{\otimes n}$ and

$$\mathcal{W}_n = \bigoplus_{i=1}^n \tilde{H}^*(X; \mathbb{Z}/p)^{\otimes i-1} \otimes DH^*(X; \mathbb{Z}/p) \otimes \tilde{H}^*(X; \mathbb{Z}/p)^{\otimes n-i},$$

where $Z^{[n]}$ denotes the n -fold fat wedge of a space Z given by

$$Z^{[n]} = \{(z_1, \dots, z_n) \in Z^n \mid z_j = * \text{ for some } 1 \leq j \leq n\}.$$

Then we have a splitting as an \mathcal{A}_p^* -module

$$(2-13) \quad \tilde{H}^*((\Sigma X)^n; \mathbb{Z}/p) \cong \mathcal{U}_n \oplus \mathcal{V}_n \oplus \mathcal{W}_n.$$

Let $\mathcal{K}_n: \tilde{H}^*(X; \mathbb{Z}/p)^{\otimes n} \rightarrow H^*(P_n(X); \mathbb{Z}/p)$ denote the following composite:

$$\tilde{H}^*(X; \mathbb{Z}/p)^{\otimes n} \xrightarrow{\sigma^{\otimes n}} H^*(\Sigma X; \mathbb{Z}/p)^{\otimes n} \cong H^*((\Sigma X)^{(n)}; \mathbb{Z}/p) \xrightarrow{\rho_n^*} H^*(P_n(X); \mathbb{Z}/p).$$

Then by [6, Theorem 3.5], there are $\tilde{a} \in \mathcal{V}_n$ and $\tilde{b} \in \mathcal{W}_n$ with $a = \mathcal{K}_n(\tilde{a})$ and $b = \mathcal{K}_n(\tilde{b})$.

Now we set $\lambda_n^*(\alpha_i) = c_i + d_i + e_i$ with respect to the splitting (2-13) for $1 \leq i \leq q$, where $\lambda_n: (\Sigma X)^n \rightarrow P_n(X)$ denotes the composite of ψ_n with the obvious projection $\omega_n: (\Sigma X)^n \rightarrow J_n(\Sigma X)$. From the same reason as Hemmi [6, Lemma 4.8], we have

$$\sum_{i=1}^q \theta_i(d_i) = \sum_{\tau \in \Sigma_n} \tau(\tilde{a}) = \lambda_n^*(a),$$

and so

$$\lambda_n^*\left(\sum_{i=1}^q \theta_i(\mathcal{K}_n(d_i))\right) = \sum_{\tau \in \Sigma_n} \tau\left(\sum_{i=1}^q \theta_i(d_i)\right) = n! \sum_{\tau \in \Sigma_n} \tau(\tilde{a}) = n!(\lambda_n^*(a)),$$

which implies

$$(2-14) \quad a = \frac{1}{n!} \sum_{i=1}^q \theta_i(\mathcal{K}_n(d_i))$$

by [6, Lemma 4.7]. If we put

$$\nu_i = \frac{1}{n!} \mathcal{K}_n(d_i) \in D^n H^*(P_n(X); \mathbb{Z}/p)$$

for $1 \leq i \leq q$, then by (2-14),

$$\sum_{i=1}^q \theta_i(\alpha_i - \nu_i) = b,$$

which completes the proof. \square

Proof of Theorem 2.6 From the construction of the space $\mathcal{M}(X)$ in Hemmi [8, Section 2], we have a space $\mathcal{N}(X)$ and the following homotopy commutative diagram:

$$(2-15) \quad \begin{array}{ccccccc} P_{p-2}(X) & \xrightarrow{\xi} & \mathcal{N}(X) & \xrightarrow{\eta} & \mathcal{M}(X) & & \\ & & \downarrow \zeta & & \downarrow \kappa & & \\ P_n(X) & \xrightarrow{\iota_n} & \cdots & \xrightarrow{\iota_{p-3}} & P_{p-2}(X) & \xrightarrow{\iota_{p-2}} & P_{p-1}(X) \xrightarrow{\iota_{p-1}} P_p(X). \end{array}$$

By Theorem 2.1 (2) and [8, page 593], we have that $M \subset R^*(X)$ is closed under the action of \mathcal{A}_p^* with $\eta^*(M) = 0$, which implies that $\eta^*|_{R^*(X)}: R^*(X) \rightarrow H^*(\mathcal{N}(X); \mathbb{Z}/p)$ induces an \mathcal{A}_p^* -homomorphism $\mathcal{F}: A^*(X) = R^*(X)/M \rightarrow H^*(\mathcal{N}(X); \mathbb{Z}/p)$. Then by applying the mod p cohomology to the diagram (2-15), we have the following commutative diagram of unstable \mathcal{A}_p^* -algebras and \mathcal{A}_p^* -homomorphisms:

$$\begin{array}{ccccc} A^*(X) & \xrightarrow{\mathcal{F}} & H^*(\mathcal{N}(X); \mathbb{Z}/p) & \xleftarrow{\zeta^*} & H^*(P_{p-1}(X); \mathbb{Z}/p) \\ & & \downarrow \xi^* & & \downarrow \iota_{p-2}^* \\ & & H^*(P_{p-2}(X); \mathbb{Z}/p) & \xlongequal{\quad} & H^*(P_{p-2}(X); \mathbb{Z}/p) \\ & & & & \downarrow \iota_{p-3}^* \\ & & & & \vdots \\ & & & & \downarrow \iota_n^* \\ & & & & H^*(P_n(X); \mathbb{Z}/p). \end{array}$$

First we assume $1 \leq n \leq p-2$. Put $\mathcal{G}_n(\alpha_i) = \beta_i$ for $1 \leq i \leq q$, where $\mathcal{G}_n: A^*(X) \rightarrow H^*(P_n(X); \mathbb{Z}/p)$ is the composite given by $\mathcal{G}_n = \iota_n^* \dots \iota_{p-3}^* \zeta^* \mathcal{F}$. Then by applying \mathcal{G}_n to (2-11), we have

$$\sum_{i=1}^q \theta_i(\beta_i) \in DH^*(P_n(X); \mathbb{Z}/p),$$

and so by Lemma 2.7, there are decomposable classes $\tilde{\nu}_i \in DH^*(P_n(X); \mathbb{Z}/p)$ for $1 \leq i \leq q$ with

$$(2-16) \quad \sum_{i=1}^q \theta_i(\tilde{\alpha}_i - \tilde{\nu}_i) = 0.$$

If we choose decomposable classes $\nu_i \in DA^*(X)$ to satisfy $\mathcal{G}_n(\nu_i) = \tilde{\nu}_i$ for $1 \leq i \leq q$, then by (2-16),

$$\sum_{i=1}^q \theta_i(\alpha_i - \nu_i) \in D^{n+1}A^*(X),$$

which completes the proof in the case of $1 \leq n \leq p-2$.

Next let us consider the case of $n = p-1$. Put $\mathcal{F}(\alpha_i) = \tilde{\alpha}_i \in H^*(\mathcal{N}(X); \mathbb{Z}/p)$ for $1 \leq i \leq q$. Then we have

$$\sum_{i=1}^q \theta_i(\tilde{\alpha}_i) \in DH^*(\mathcal{N}(X); \mathbb{Z}/p).$$

By [8, Proposition 5.2], we see that $\mathcal{F}(A^*(X))$ is contained in $\zeta^*(H^*(P_{p-1}(X); \mathbb{Z}/p))$, and so we can choose $\beta_i \in H^*(P_{p-1}(X); \mathbb{Z}/p)$ and $a \in DH^*(P_{p-1}(X); \mathbb{Z}/p)$ with $\zeta^*(\beta_i) = \tilde{\alpha}_i$ and

$$\zeta^*(a) = \sum_{i=1}^q \theta_i(\tilde{\alpha}_i)$$

for $1 \leq i \leq q$. Then we can set

$$\sum_{i=1}^q \theta_i(\beta_i) = a + b$$

with $\zeta^*(b) = 0$, and by [8, Lemma 5.1], we have $b \in S_{p-1}$. By Lemma 2.7, there are decomposable classes $\mu_i \in DH^*(P_{p-1}(X); \mathbb{Z}/p)$ for $1 \leq i \leq q$ with

$$\sum_{i=1}^q \theta_i(\beta_i - \mu_i) = b.$$

Let $\nu_i \in DA^*(X)$ with $\mathcal{F}(\nu_i) = \zeta^*(\mu_i)$ for $1 \leq i \leq q$. Then we have

$$\sum_{i=1}^q \theta_i(\alpha_i - \nu_i) \in D^p A^*(X),$$

which implies the required conclusion. This completes the proof of [Theorem 2.6](#). \square

3 Proofs of [Theorem A](#) and [Theorem B](#)

In this section, we assume that A^* is an unstable \mathcal{A}_p^* -algebra which is the truncated polynomial algebra at height $p + 1$ given by

$$(3-1) \quad A^* = T^{[p+1]}[y_1, \dots, y_l] \quad \text{with } \deg y_i = 2m_i$$

for $1 \leq i \leq l$, where $1 \leq m_1 \leq \dots \leq m_l$. Moreover, we choose the generators $\{y_i\}$ to satisfy

$$(3-2) \quad \mathcal{P}^1(y_i) \in DA^* \text{ or } \mathcal{P}^1(y_i) = y_j \quad \text{for some } 1 \leq j \leq l.$$

The above is possible by the same argument as Hemmi [[5](#), Section 4].

First we prove the following result:

Proposition 3.1 *Suppose that A^* is a \mathcal{D}_n -algebra and $1 \leq i \leq l$. If $\mathcal{P}^1(y_i)$ contains the term y_j^t for some $1 \leq j \leq l$ and $1 \leq t \leq n$, then $y_j = \mathcal{P}^1(y_k)$ for some $1 \leq k \leq l$.*

Proof If $t = 1$, then by (3-2), the result is clear. Let t be the smallest integer with $1 < t \leq n$ such that the term y_j^t is contained in $\mathcal{P}^1(y_{i'})$ for some $1 \leq i' \leq l$. Then by (3-2), we have $\mathcal{P}^1(y_{i'}) \in DA^*$. Since A^* is a \mathcal{D}_n -algebra, there is a decomposable class $\nu \in DA^*$ with $\mathcal{P}^1(y_{i'} - \nu) \in D^{n+1}A^*$. This implies that $\mathcal{P}^1(\nu)$ contains the term y_j^t , and so there is one of the generators $y_{i''}$ of (3-1) for $1 \leq i'' \leq l$ such that $\mathcal{P}^1(y_{i''})$ contains the term y_j^s for some $1 \leq s < t$. Then we have a contradiction, and so $t = 1$. This completes the proof. \square

In the proof of [Theorem A](#), we need the following result:

Proposition 3.2 *Let p be an odd prime. If A^* is a \mathcal{D}_n -algebra with $n > (p - 1)/2$, then the indecomposable module QA^* of A^* satisfies the following:*

(1) If $a \geq 0$, $b > 0$ and $0 < c < p$, then

$$(3-3) \quad QA^{2p^a(pb+c)} = \mathcal{P}^{p^a t} QA^{2p^a(p(b-t)+c+t)}$$

for $1 \leq t \leq \min \{b, p-c\}$ and

$$(3-4) \quad \mathcal{P}^{p^a t} QA^{2p^a(pb+c)} = 0 \quad \text{in } QA^{2p^a(p(b+t)+c-t)}$$

for $c \leq t < p$.

(2) If $a \geq 0$ and $0 < c < p$, then

$$(3-5) \quad \mathcal{P}^{p^a t} : QA^{2p^a c} \longrightarrow QA^{2p^a(tp+c-t)}$$

is an isomorphism for $1 \leq t < c$.

Proof First we consider the case of $a = 0$. Let us prove (1) by downward induction on b . If b is large enough, then the result is clear since $QA^{2(pb+c)} = 0$. Assume that y_j is one of the generators of (3-1) for $1 \leq j \leq l$ and $\deg y_j = 2(pb+c)$ with $b > 0$ and $0 < c < p$. By inductive hypothesis, we can assume that if $f > b$ and $0 < g < p$, then

$$(3-6) \quad QA^{2(pf+g)} = \mathcal{P}^t QA^{2(p(f-1)+g+1)}$$

for $1 \leq t \leq \min \{f, p-g\}$. If we put

$$\beta = \frac{1}{pb+c} \mathcal{P}^{pb+c-1}(y_j) \in A^{2(p(pb+c-1)+1)},$$

then by (3-6), we have

$$\beta - \mathcal{P}^{p-1}(\gamma) \in DA^*$$

for some $\gamma \in QA^{2p(p(b-1)+1)}$. Since A^* is a \mathcal{D}_n -algebra,

$$(3-7) \quad \beta - \frac{1}{pb+c} \mathcal{P}^{pb+c-1}(\mu) - \mathcal{P}^{p-1}(\gamma - \nu) \in D^{n+1}A^*$$

for some decomposable classes $\mu \in DA^{2(pb+c)}$ and $\nu \in DA^{2p(p(b-1)+1)}$. If we apply \mathcal{P}^1 to (3-7), then $y_j^p = \mathcal{P}^1(\xi)$ for some $\xi \in D^{n+1}A^*$ since $\mathcal{P}^{pb+c}(\mu) = \mu^p = 0$ in A^* and $\mathcal{P}^1 \mathcal{P}^{p-1} = p \mathcal{P}^p = 0$. Then for some generator y_i , $\mathcal{P}^1(y_i)$ must contain some y_j^t with $1 \leq t \leq p$ and $t+n=p$. By the assumption of $n > (p-1)/2$, we have $1 \leq t \leq n$, which implies that $y_j = \mathcal{P}^1(y_k)$ for some $1 \leq k \leq l$ by Proposition 3.1. By iterating this argument, we have (3-3).

Now (3-4) follows from (3-3). In fact, if y_j is a generator in (3-1) with $\deg y_j = 2(pb+c)$ for some $b > 0$ and $0 < c < p$, then we show that $\mathcal{P}^c(y_j) = 0$. If $b+c < p$, then by (3-3), we have $y_j = \mathcal{P}^b(\kappa)$ for $\kappa \in QA^{2(b+c)}$, which implies that

$$(3-8) \quad \mathcal{P}^c(y_j) = \mathcal{P}^c \mathcal{P}^b(\kappa) = \binom{b+c}{b} \kappa^p = 0$$

in $QA^{2p(b+c)}$. On the other hand, if $p \leq b + c$, then by (3–3), we have $y_j = \mathcal{P}^{p-c}(\zeta)$ for $\zeta \in QA^{2p(b+c-p+1)}$, and so

$$(3-9) \quad \mathcal{P}^c(y_j) = \mathcal{P}^c \mathcal{P}^{p-c}(\zeta) = \binom{p}{c} \mathcal{P}^p(\zeta) = 0.$$

Next we show (2) with $a = 0$. We only have to show that \mathcal{P}^{c-1} is a monomorphism on QA^{2c} . Let y_j be a generator in (3–1) such that $\deg y_j = 2c$ with $0 < c < p$. Suppose contrarily that $\mathcal{P}^{c-1}(y_j) = 0$ in $QA^{2(c-1)p+1}$. Since A^* is a \mathcal{D}_n -algebra, we have that

$$\mathcal{P}^{c-1}(y_j - \mu) \in D^{n+1}A^{2(c-1)p+1}$$

for some decomposable class $\mu \in DA^{2c}$. Then by a similar argument to the proof of (1), we have that $y_j = \mathcal{P}^1(y_k)$ for some $1 \leq k \leq l$ with $\deg y_k = 2(c - p + 1)$, which is impossible for dimensional reasons. This completes the proof of Proposition 3.2 in the case of $a = 0$.

Let I denote the ideal of A^* generated by y_i with $m_i \not\equiv 0 \pmod{p}$. Then for dimensional reasons and by (3–8) and (3–9), we see that I is closed under the action of \mathcal{A}_p^* , which implies that A^*/I is an unstable \mathcal{A}_p^* -algebra given by

$$A^*/I = T^{[p+1]}[y_{i_1}, \dots, y_{i_q}] \quad \text{with } m_{i_d} \equiv 0 \pmod{p}$$

for $1 \leq d \leq q$. Set $m_{i_d} = ph_d$ with $h_d \geq 1$ for $1 \leq d \leq q$. Let B^* denote the truncated polynomial algebra at height $p + 1$ given by

$$B^* = T^{[p+1]}[z_1, \dots, z_q] \quad \text{with } \deg z_d = h_d$$

for $1 \leq d \leq q$. If we define a map $\tilde{\mathcal{L}}: \{y_{i_1}, \dots, y_{i_q}\} \rightarrow B^*$ by $\tilde{\mathcal{L}}(y_{i_d}) = z_d$ for $1 \leq d \leq q$, then $\tilde{\mathcal{L}}$ is extended to an isomorphism $\mathcal{L}: A^*/I \rightarrow B^*$. Moreover, B^* admits an unstable \mathcal{A}_p^* -algebra structure by the action $\mathcal{P}^r(z_d) = \mathcal{L}(\mathcal{P}^{pr}(y_{i_d}))$ for $r \geq 1$. Then we can show that B^* is a \mathcal{D}_n -algebra concerning this structure since so is A^* . From the above arguments, we have the required results for B^* in the case of $a = 0$, which implies that A^* satisfies the required results for $a = 1$. By repeating these arguments, we can show that A^* satisfies the desired conclusions of Proposition 3.2 for any $a \geq 0$. This completes the proof. \square

Now we prove Theorem A as follows:

Proof of Theorem A By Browder [3, Theorem 8.6], $H^*(X; \mathbb{Z}/p)$, the mod p cohomology, is an exterior algebra in (2–1). Let \tilde{X} be the universal cover of X . From the

proof of [10, Lemma 3.9], we have that \tilde{X} is a simply connected A_p -space admitting an AC_n -form. It is enough to prove [Theorem A](#) for \tilde{X} since $X \simeq \tilde{X} \times T$ for a torus T by Kane [14, page 24]. By [Theorem 2.2](#) and [Theorem 2.6](#), we have that $A^*(\tilde{X})$ is a \mathcal{D}_n -algebra. Then by [Theorem 2.1](#) (3) and [Proposition 3.2](#), we have the required conclusion. This completes the proof of [Theorem A](#). \square

By using [Theorem A](#), we prove [Theorem B](#) as follows:

Proof of Theorem B We proceed by using a similar way to the proof of [6, Theorem 1.1]. Since $X \simeq \tilde{X} \times T$ for a torus T as in the proof of [Theorem A](#), the Steenrod operations \mathcal{P}^j act trivially on $QH^*(\tilde{X}; \mathbb{Z}/p)$ for $j \geq 1$. By [Theorem A](#), if $QH^{2m-1}(\tilde{X}; \mathbb{Z}/p) \neq 0$, then $m = p^a$ for some $a \geq 1$, and so the mod p cohomology of \tilde{X} is an exterior algebra in (2-1), where $m_i = p^{a_i}$ with $a_i \geq 1$ for $1 \leq i \leq l$.

Let $P_{p-1}(\tilde{X})$ be the $(p-1)$ -th projective space of \tilde{X} . Then by (2-2), there is an ideal $S_{p-1} \subset H^*(P_{p-1}(\tilde{X}); \mathbb{Z}/p)$ closed under the action of \mathcal{A}_p^* with

$$H^*(P_{p-1}(\tilde{X}); \mathbb{Z}/p)/S_{p-1} \cong T^{[p]}[y_1, \dots, y_l],$$

where $T^{[p]}[y_1, \dots, y_l]$ is the truncated polynomial algebra at height p generated by $y_i \in H^{2p^{a_i}}(P_{p-1}(\tilde{X}); \mathbb{Z}/p)$ with $\iota_1^* \dots \iota_{p-2}^*(y_i) = \sigma(x_i) \in H^{2p^{a_i}}(\Sigma\tilde{X}; \mathbb{Z}/p)$. Moreover, we have that the composite

$$(3-10) \quad H^t(P_p(\tilde{X}); \mathbb{Z}/p) \xrightarrow{\iota_{p-1}^*} H^t(P_{p-1}(\tilde{X}); \mathbb{Z}/p) \longrightarrow T^{[p]}[y_1, \dots, y_l]$$

is an isomorphism for $t < 2p^{a_1+1}$ and an epimorphism for $t < 2(p^{a_1+1} + p^{a_1} - 1)$ by [6, page 106, (4.10)]. As in [6, page 106, (4.11)], we can show

$$(3-11) \quad \text{Im } \mathcal{P}^{p^{a_1}} \cap H^t(P_p(\tilde{X}); \mathbb{Z}/p) = 0$$

for $t \leq 2p^{a_1+1}$. In fact, by (3-10) and for dimensional reasons, we have

$$\text{Im } \beta \cap H^t(P_p(\tilde{X}); \mathbb{Z}/p) = 0$$

$$\text{Im } \mathcal{P}^1 \cap H^t(P_p(\tilde{X}); \mathbb{Z}/p) = 0$$

for $t \leq 2p^{a_1+1}$, which implies (3-11) by Liulevicius [22] or Shimada–Yamanoshita [24]. Now we can choose $w_1 \in H^{2p^{a_1}}(P_p(\tilde{X}); \mathbb{Z}/p)$ with $\iota_{p-1}^*(w_1) = y_1$ by (3-10), and we have $w_1^p = \mathcal{P}^{p^{a_1}}(w_1) = 0$ by (3-11). Then we have a contradiction by using the same argument as the proof of [6, Theorem 1.1], and so \tilde{X} is contractible, which implies that X is a torus. This completes the proof of [Theorem B](#). \square

To show [Theorem C](#), we need the following definition:

Definition 3.3 Assume that X is an A_n -space and Y is a space.

- (1) An AC_n -form on a map $\phi: Y \rightarrow X$ is a family of maps $\{R_i: \Gamma_i \times Y^i \rightarrow X\}_{1 \leq i \leq n}$ with the conditions $R_1(*, y) = \phi(y)$ for $y \in Y$ and (2-6)–(2-7).
- (2) A quasi C_n -form on a map $\kappa: \Sigma Y \rightarrow \Sigma X$ is a family of maps $\{\zeta_i: J_i(\Sigma Y) \rightarrow P_i(X)\}_{1 \leq i \leq n}$ with the conditions $\zeta_1 = \kappa$ and (2-9).

By using the same argument as the proof of Theorem 2.2 (1), we can prove the following result:

Theorem 3.4 Assume that X is an A_n -space, Y is a space and $\phi: Y \rightarrow X$ is a map. Then any AC_n -form on ϕ induces a quasi C_n -form on $\Sigma\phi$.

Now we prove Theorem C as follows:

Proof of Theorem C First we show that if X admits an AC_n -form, then $nm_l \leq p$.

We prove by induction on n . If $n = 1$, then the result is proved by Hubbuck–Mimura [11] and Iwase [13, Proposition 0.7]. Assume that the result is true for $n - 1$. Then by inductive hypothesis, we have $(n - 1)m_l \leq p$. Now we assume that X admits an AC_n -form with

$$(3-12) \quad (n - 1)m_l \leq p < nm_l.$$

Then we show a contradiction.

Let \tilde{X} be the universal covering space of X . Then \tilde{X} is a simply connected A_p -space mod p homotopy equivalent to

$$(3-13) \quad S^{2m_1-1} \times \cdots \times S^{2m_l-1} \quad \text{with } 1 < m_1 \leq \cdots \leq m_l$$

and the multiplication of \tilde{X} admits an AC_n -form by [10, Lemma 3.9]. Now we can set that

$$A^*(\tilde{X}) = T^{[p+1]}[y_1, \dots, y_l] \quad \text{with } \deg y_i = 2m_i$$

for $1 \leq i \leq l$, where $1 < m_1 \leq \cdots \leq m_l \leq p$. By Theorem 2.2 and Theorem 2.6, $A^*(\tilde{X})$ is a \mathcal{D}_n -algebra.

First we consider the case of $m_l < p$. Let J be the ideal of $A^*(\tilde{X})$ generated by y_i for $1 \leq i \leq l - 1$. Then we see that

$$(3-14) \quad \mathcal{P}^1(y_i) \notin J \quad \text{for some } 1 \leq i \leq l.$$

In fact, if we assume that $\mathcal{P}^1(y_i) \in J$ for any $1 \leq i \leq l$, then $\mathcal{P}^1(y_l) \in J$ and $\mathcal{P}^1(J) \subset J$. This implies that

$$y_l^p = \mathcal{P}^{m_l}(y_l) = \frac{1}{m_l!}(\mathcal{P}^1)^{m_l}(y_l) \in J,$$

which is a contradiction, and so we have (3–14). Then for dimensional reasons and by (3–12),

$$2(n-1)m_l < \deg \mathcal{P}^1(y_i) < 2(n+1)m_l,$$

which implies that $\mathcal{P}^1(y_i)$ contains the term ay_l^n with $a \neq 0$ in \mathbb{Z}/p by (3–14). By Proposition 3.1, we have $y_l \in \mathcal{P}^1 QA^{2(m_l-p+1)}(\tilde{X})$, which causes a contradiction since $m_l < p$.

Next let us consider the case of $m_l = p$. In this case, (3–12) is equivalent to $n = 2$, and so \tilde{X} is assumed to have an AC_2 -form. Then from the same arguments as above, we have that $A^*(\tilde{X})$ is a \mathcal{D}_2 -algebra. By Kanemoto [15, Lemma 3], there is a generator $y_k \in QA^{2(p-1)}(\tilde{X})$ for some $1 \leq k < l$. Let K be the ideal of $A^*(\tilde{X})$ generated by y_i with $i \neq k$. From the same reason as (3–14), we see that $\mathcal{P}^1(y_i) \notin K$ for some $1 \leq i \leq l$. Then for dimensional reasons, we see that $\mathcal{P}^1(y_i)$ contains the term by_k^2 with $b \neq 0$ in \mathbb{Z}/p . By Proposition 3.1, we have a contradiction, and so \tilde{X} does not admit an AC_2 -form.

Next we show that if $nm_l \leq p$, then X admits an AC_n -form. Since it is clear for $n = 1$ or $m_l = 1$, we can assume that $nm_l < p$. Let Y denote the wedge sum of spheres given by

$$Y = (S^{2m_1-1} \vee \dots \vee S^{2m_l-1})_{(p)}$$

with the inclusion $\phi: Y \rightarrow X$. First we construct an AC_n -form $\{R_i: \Gamma_i \times Y^i \rightarrow X\}_{1 \leq i \leq n}$ on $\phi: Y \rightarrow X$.

Suppose inductively that $\{R_i\}_{1 \leq i < t}$ are constructed for some $t \leq n$. Then the obstructions for the existence of R_t belong to the following cohomology groups for $j \geq 1$:

$$(3-15) \quad H^{j+1}(\Gamma_t \times Y^t, \partial\Gamma_t \times Y^t \cup \Gamma_t \times Y^{[t]}; \pi_j(X)) \cong \tilde{H}^{j+2}((\Sigma Y)^{(t)}; \pi_j(X))$$

since $\Gamma_t \times Y^t / (\partial\Gamma_t \times Y^t \cup \Gamma_t \times Y^{[t]}) \simeq \Sigma^{t-1} Y^{(t)}$. This implies that (3–15) is non-trivial only if j is an even integer with $j < 2p - 2$ since

$$\Sigma Y \simeq (S^{2m_1} \vee \dots \vee S^{2m_l})_{(p)}$$

and $tm_l \leq nm_l < p$. On the other hand, according to Toda [27, Theorem 13.4], $\pi_j(X) = 0$ for any even integer j with $j < 2p - 2$ since X is given by (3–13). Thus

(3–15) is trivial for all j , and we have a map R_i . This completes the induction, and we have an AC_n -form $\{R_i\}_{1 \leq i \leq n}$ on $\phi: Y \rightarrow X$.

Since X is an H -space, there is a map $\beta: \Omega\Sigma X \rightarrow X$ with $\beta\alpha \simeq 1_X$, where $\alpha: X \rightarrow \Omega\Sigma X$ denotes the adjoint of $1_{\Sigma X}: \Sigma X \rightarrow \Sigma X$. Moreover, ΣY is a retract of ΣX , and so we have a map $\nu: \Sigma X \rightarrow \Sigma Y$ with $\nu(\Sigma\phi) \simeq 1_{\Sigma Y}$. Put $\lambda = \beta\theta: X \rightarrow X$, where $\theta: X \rightarrow \Omega\Sigma X$ denotes the adjoint of $(\Sigma\phi)\nu$. Then we see that λ induces an isomorphism on the mod p cohomology, and so λ is a mod p homotopy equivalence.

By Theorem 3.4, there is a quasi C_n -form $\{\zeta_i: J_i(\Sigma Y) \rightarrow P_i(X)\}_{1 \leq i \leq n}$ on $\Sigma\phi: \Sigma Y \rightarrow \Sigma X$. Let $\xi_i: J_i(\Sigma X) \rightarrow P_i(X)$ be the map defined by $\xi_i = \zeta_i J_i(\nu(\Sigma\lambda^{-1}))$ for $1 \leq i \leq n$, where $\lambda^{-1}: X \rightarrow X$ denotes the homotopy inverse of λ . Then the family $\{\xi_i\}_{1 \leq i \leq n}$ satisfies that $\xi_i|_{J_{i-1}(\Sigma X)} = \iota_{i-1}\xi_{i-1}$ for $2 \leq i \leq n$ and $\xi_1 = (\Sigma\phi)\nu(\Sigma\lambda^{-1}) = \chi(\Sigma\theta)(\Sigma\lambda^{-1})$, where $\chi: \Sigma\Omega\Sigma X \rightarrow \Sigma X$ is the evaluation map. Since $\iota_1(\Sigma\beta) \simeq \iota_1\chi: \Sigma\Omega\Sigma X \rightarrow P_2(X)$ by Hemmi [9, Lemma 2.1], we have $\xi_2|_{\Sigma X} = \iota_1\xi_1 \simeq \iota_1$. Let $\psi_i: J_i(\Sigma X) \rightarrow P_i(X)$ be the map defined by $\psi_1 = 1_{\Sigma X}$ and $\psi_i = \xi_i$ for $2 \leq i \leq n$. Then the family $\{\psi_i\}_{1 \leq i \leq n}$ satisfies (2–8)–(2–9). By Theorem 2.2 (2) and Remark 2.3, we have an AC_n -form $\{Q_i: \Gamma_i \times X^i \rightarrow X\}_{1 \leq i \leq n}$ on X with (2–5)–(2–7). This completes the proof of Theorem C. \square
