# Deformed multiplication in the semigroup $\mathcal{PT}_n$

### Galyna Tsyaputa

#### Abstract

Pairwise non isomorphic semigroups obtained from the semigroup  $\mathcal{PT}_n$  of all partial transformations by the deformed multiplication proposed by Ljapin are classified.

### 1 Introduction

Let X and Y be two nonempty sets, S be the set of maps from X to Y. Fix some  $\alpha: Y \to X$  and define the multiplication of elements in S in the following way:  $\phi \circ \psi = \phi \alpha \psi$  (the composition of the maps is from left to right). The action defined by this rule is associative. In his famous monograph [1, p.353] Ljapin set the problem of investigation of the properties of this semigroup depending on the restrictions on set S and map  $\alpha$ .

Magill [2] studies this problem in the case when X and Y are topological spaces and the maps are continuous. In particular under the assumption that  $\alpha$  be onto he describes the automorphisms of such semigroups and determines the isomorphism criterion.

A bit later Sullivan [3] proves that if  $|Y| \leq |X|$  then Ljapin's semigroup is embedding into transformation semigroup on the set  $X \cup \{a\}$ ,  $a \notin X$ .

For us the important case is if X = Y,  $T_X$  is a transformation semigroup on the set X,  $\alpha \in T_X$ . Symons [4] establishes the isomorphism criterion for such semigroups and investigates the properties of their automorphisms.

The latter problem may be generalized to arbitrary semigroup S: for a fixed  $a \in S$  define the operation  $*_a$  via  $x *_a y = xay$ . The obtained semigroup is denoted by  $(S, *_a)$  and operation  $*_a$  is called the multiplication deformed by element a (or just the deformed multiplication).

In the paper we classify with respect to isomorphism all semigroups which are obtained from the semigroup of all partial transformations of an n-element set by the deformed multiplication.

## 2 $\mathcal{PT}_n$ with the deformed multiplication

Let  $\mathcal{PT}_n$  be the semigroup of all partial transformations of the set  $N = \{1, 2, ..., n\}$ . For arbitrary partial transformation  $a \in \mathcal{PT}_n$  denote by dom(a) the domain of a, and by ran(a) its image. The value |ran(a)| is called the rank of a and is denoted by rank(a). Denote

 $Z(a) = N \setminus \text{dom}(a)$  the set of those elements on which transformation a is not defined, and denote  $z_a$  the cardinality of this set. The type of  $a \in \mathcal{PT}_n$  we call the set  $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ , where  $\alpha_k$  is the number of those elements  $y \in N$ , the full inverse image  $a^{-1}(y)$  of which contains exactly k elements. It is obvious that  $1 \cdot \alpha_1 + 2 \cdot \alpha_2 + \cdots + n \cdot \alpha_n = |\operatorname{dom}(a)|$ , and the sum  $\alpha_1 + \alpha_2 + \cdots + \alpha_n$  is equal to the rank of a.

**Definition 1.** Element  $x \in \mathcal{S}$  is called left (right) annihilator of semigroup  $\mathcal{S}^0$  provided that xs = 0 (sx = 0),  $s \in \mathcal{S}$ .

Element which is both the left and the right annihilator is called the annihilator of semigroup S.

**Proposition 1.** Transformations  $x \in \mathcal{PT}_n$  such that  $\operatorname{ran}(x) \subset Z(a)$  are left annihilators of semigroup  $(\mathcal{PT}_n, *_a)$ . The number of left annihilators equals  $(z_a + 1)^n$ .

Transformations  $y \in \mathcal{PT}_n$  such that  $Z(y) \supset \operatorname{ran}(a)$  are right annihilators of semigroup  $(\mathcal{PT}_n, *_a)$ . The number of right annihilators equals  $(n+1)^{n-\operatorname{rank}(a)}$ .

Transformations  $c \in \mathcal{PT}_n$  such that  $\operatorname{ran}(c) \subset Z(a)$  and  $Z(c) \supset \operatorname{ran}(a)$  are annihilators of  $(\mathcal{PT}_n, *_a)$ , moreover, the number of annihilators equals  $(z_a + 1)^{n - \operatorname{rank}(a)}$ .

Proof. Let  $x \in \mathcal{PT}_n$  be left annihilator of  $(\mathcal{PT}_n, *_a)$ . This means that for arbitrary u from  $\mathcal{PT}_n$   $x *_a u = 0$  or, what is the same,  $xa \cdot u = 0$ . Therefore xa is left zero of semigroup  $\mathcal{PT}_n$ , that is, a nowhere defined map. The latter is possible if and only if  $\operatorname{ran}(x) \subset Z(a)$ . Evidently, the condition  $\operatorname{ran}(x) \subset Z(a)$  is sufficient for partial transformation x be the left annihilator of  $(\mathcal{PT}_n, *_a)$ . Now it is clear, that the number of such transformations is equal to  $(z_a + 1)^n$ .

Let  $y \in \mathcal{PT}_n$  be the right annihilator of semigroup  $(\mathcal{PT}_n, *_a)$ . Then for any v from  $\mathcal{PT}_n$   $v \cdot ay = 0$  and ay is right zero of semigroup  $\mathcal{PT}_n$ , that is, nowhere defined map. This is equivalent to  $Z(y) \supset \operatorname{ran}(a)$ . Therefore right annihilators of semigroup  $(\mathcal{PT}_n, *_a)$  are those partial transformations  $\mathcal{PT}_n$  which are defined only in elements  $N \setminus \operatorname{ran}(a)$ . It is clear that the number of such transformations equals  $(n+1)^{n-\operatorname{rank}(a)}$ .

Now the statement about annihilators follows from the definition and the above arguments.  $\Box$ 

On semigroup  $(\mathcal{PT}_n, *_a)$  define the equivalence relation  $\sim_a$  by the rule:  $x \sim_a y$  if and only if  $x *_a u = y *_a u$  for all  $u \in \mathcal{PT}_n$ . Analogously on  $(\mathcal{PT}_n, *_b)$  define the relation  $\sim_b$ .

**Lemma 1.** For an arbitrary isomorphism  $\varphi : (\mathcal{PT}_n, *_a) \to (\mathcal{PT}_n, *_b) \varphi(x) \sim_b \varphi(y)$  if and only if  $x \sim_a y$ .

Proof. In fact, let  $\varphi: (\mathcal{PT}_n, *_a) \to (\mathcal{PT}_n, *_b)$  be isomorphism and  $x \sim_a y$ . Then for all  $u \in \mathcal{PT}_n$ :  $x*_a u = y*_a u$ , therefore  $\varphi(x)*_b \varphi(u) = \varphi(y)*_b \varphi(u)$ . However  $\varphi(u)$  runs over the whole set  $\mathcal{PT}_n$ , hence  $\varphi(x) \sim_b \varphi(y)$ . Since the inverse map  $\varphi^{-1}: (\mathcal{PT}_n, *_b) \to (\mathcal{PT}_n, *_a)$  is also isomorphism,  $\varphi(x) \sim_b \varphi(y)$  implies  $x \sim_a y$ . Therefore,  $x \sim_a y$  if and only if  $\varphi(x) \sim_b \varphi(y)$ .

**Lemma 2.**  $x \sim_a y$  if and only if xa = ya.

*Proof.* Obviously, the equality xa = ya implies  $x \sim_a y$ . Now let  $xa \neq ya$ . Then there exists k in N, such that  $(xa)(k) \neq (ya)(k)$ . Chose element u in  $\mathcal{PT}_n$  which has different images in the points (xa)(k) and (ya)(k). Then  $x *_a u = xau$  and  $y *_a u = yau$  have different images in k. Hence  $x *_a u \neq y *_a u$  and  $x \sim_a y$ .

**Theorem 1.** Semigroups  $(\mathcal{PT}_n, *_a)$  and  $(\mathcal{PT}_n, *_b)$  are isomorphic if and only if partial transformations a and b have the same type.

*Proof. Necessity.* Let  $(\mathcal{PT}_n, *_a)$  and  $(\mathcal{PT}_n, *_b)$  be isomorphic. By lemma 1 arbitrary isomorphism between  $(\mathcal{PT}_n, *_a)$  and  $(\mathcal{PT}_n, *_b)$  maps equivalence classes of the relation  $\sim_a$  into equivalence classes of the relation  $\sim_b$ . Therefore for equivalence relations  $\sim_a$  and  $\sim_b$  cardinalities and the number of equivalence classes must be equal. We show that by the cardinalities of the classes of the relation  $\sim_a$  the type  $(\alpha_1, \alpha_2, \ldots, \alpha_n)$  of transformation a can be found uniquely.

Denote  $\rho_a$  the partition of set  $\{1, 2, ..., n\}$  induced by  $a \in \mathcal{PT}_n$  (that is, l and m belong to the same block of the partition  $\rho_a$  provided that a(l) = a(m); Z(a) forms a separate block). We count the cardinality of equivalence class  $\overline{x_0} = \{x | xa = x_0a\}$  of the relation  $\sim_a$  for the fixed transformation  $x_0 \in \mathcal{PT}_n$ . Consider element

$$y := x_0 a = \begin{pmatrix} i_1 & i_2 & \dots & i_p & i_{p+1} & \dots & i_n \\ y_1 & y_2 & \dots & y_p & \varnothing & \dots & \varnothing \end{pmatrix}.$$

Obviously  $y_i$  belongs to the image of a, i = 1, ..., p. Denote  $N_a(a_i)$  the block of the partition  $\rho_a$  which is defined by  $a_i$  in the image of a. Denote  $n_a(a_i)$  the cardinality of this block. The equality xa = y is equivalent to that for every i  $(xa)(i) = y_i$ , or, what is the same,  $x(i) \in N_a(y_i)$ . Hence x(i) can be chosen in  $n_a(y_i)$  ways, i = 1, ..., p. For i = p + 1, ..., n the meaning of x(i) can be chosen in  $z_a + 1$  ways. Since the images of x in different points are chosen independently, partial transformation x can be defined in

$$n_a(y_1)n_a(y_2)\dots n_a(y_p)(z_a+1)^{n-p}$$
 (1)

ways, and this gives the cardinality of class  $\overline{x_0}$ .

It is clear that  $\overline{0}$  is the set of all left annihilators of the semigroup  $(\mathcal{PT}_n, *_a)$ . By proposition 1 the cardinality of class  $\overline{0}$  equals  $(z_a + 1)^n$ . Hence the value  $z_a$  is defined by abstract property the semigroup  $(\mathcal{PT}_n, *_a)$ . Denote m the smallest cardinality of the blocks of the partition  $\rho_a$ . Then the cardinality of the equivalence class of the relation  $\sim_a$  is the least if in (1) all multipliers are equal to  $\min(m, z_a + 1)$ . Consider the corresponding cases.

Let  $m > z_a + 1$ . Then class  $\overline{0}$  is the only equivalence class of the least possible cardinality. The next larger class contains  $m(z_a + 1)^{n-1}$  transformations. Now count the number of different equivalence classes of the relation  $\sim_a$  which have the cardinality  $m(z_a + 1)^{n-1}$ . Since  $m > z_a + 1$  and this is the least of the cardinalities of the blocks of the partition  $\rho_a$ , to make the product in (1) be equal to  $m(z_a + 1)^{n-1}$  there should be p = 1 and  $n_a(y_1) = m$ . Element  $i_1$  can be chosen in n ways. We know that  $|\{t : n_a(t) = m\}| = \alpha_m$ , so  $y_1$  can have  $\alpha_m$  different meanings. Therefore, there are  $n \cdot \alpha_m$  different transformations

 $y=x_0a$ , such that the corresponding class  $\overline{x_0}$  contains  $m(z_a+1)^{n-1}$  elements. Therefore by the relation  $\sim_a$  we may define the number m and the meaning  $\alpha_m$  of the first nonzero component of the type  $(\alpha_1,\alpha_2,\ldots,\alpha_n)$  of element a. Components  $\alpha_l$  for l>m can be defined recursively. Assume that  $\alpha_1,\alpha_2,\ldots,\alpha_l$  are found. For the relation  $\sim_a$  denote C the number of equivalence classes of the cardinality  $l\cdot(z_a+1)^{n-1}$ . Then C is equal to the number of sets  $(p;i_1,i_2,\ldots,i_p)$ , where some of  $i_1,i_2,\ldots,i_p$  may coincide in general, such that

$$n_a(y_{i_1})n_a(y_{i_2})\dots n_a(y_{i_p})(z_a+1)^{n-p} = l\cdot (z_a+1)^{n-1}.$$
 (2)

Since  $\alpha_1, \alpha_2, \ldots, \alpha_{l-1}$  are known, we may find the number A of sets  $(p; i_1, i_2, \ldots, i_p)$  such that all multipliers in the left hand side of (2) are less than l. This value equals

$$\sum_{k=1}^{n} \sum_{\substack{(m_1, \dots, m_k) \\ m \le m_1, \dots, m_k \le l \\ m_1 \cdot m_2 \dots m_k = l \cdot (z_a + 1)^{n-1}}} \binom{n}{k} \prod_{j=1}^{k} \alpha_{m_j}.$$

The number of sets  $(p; i_1, i_2, \ldots, i_n)$  such that one of the multipliers in the left hand side of (2) equals l, is equal to  $n \cdot \alpha_l$ . Then  $\alpha_l$  can be found from the equality  $A + n \cdot \alpha_l = C$ .

Now let  $m \leq z_a + 1$ . Then the cardinality of the equivalence class of the relation  $\sim_a$  is the least if in (1) all multipliers are equal to m, that is, this cardinality equals  $m^n$ . Count the number of different equivalence classes  $\overline{x_0}$  of the relation  $\sim_a$  of the cardinality  $m^n$ . To make all multipliers in (1) equal to m, there should be  $n_a(y_i) = m$  for all i. However  $|\{t: n_a(t) = m\}| = \alpha_m$ . So every  $y_i$  can be chosen in  $\alpha_m$  ways. Since the meanings of  $y_i$  for different i are chosen independently, there are  $\alpha_m^n$  different  $y = x_0 a$ , such that the corresponding class  $\overline{x_0}$  contains  $m^n$  elements. Hence by the relation  $\sim_a$  we may define the number m and the meaning  $\alpha_m$  of the first non zero component of the type  $(\alpha_1, \alpha_2, \ldots, \alpha_n)$  of a.

Components  $\alpha_l$  for l > m can be found recursively applying the same arguments as above. Some changes include the following: in (2) the right hand side must be substituted with  $l \cdot m^{n-1}$ , and the number of sets  $(p; i_1, i_2, \ldots, i_n)$ , such that one of the multipliers in the left hand side of (2) equals l, and other n-1 multipliers equal m is equal to  $n \cdot \alpha_l \cdot \alpha_m^{n-1}$  (if  $z_a + 1 \neq l$  then p = n). Therefore  $\alpha_l$  can be found from the equality  $A + n \cdot \alpha_l \cdot \alpha_m^{n-1} = C$ .

Analogously we may find the type  $(\beta_1, \beta_2, \ldots, \beta_n)$  of b via the cardinalities of the equivalence classes of the relation  $\sim_b$ . Since for isomorphic semigroups  $(\mathcal{PT}_n, *_a)$  and  $(\mathcal{PT}_n, *_b)$  the number of the equivalence classes of the same cardinality coincide, and the values  $\alpha_k$  and  $\beta_k$ ,  $k = 1, \ldots, n$  are defined uniquely by the number of equivalence classes, for all k we have  $\alpha_k = \beta_k$ , that is, elements a and b have the same types.

Sufficiency. Let elements a and b have the type  $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ . Then there exist permutations  $\pi$  and  $\tau$  in  $\mathcal{S}_n$  such that  $b = \tau \alpha \pi$ . The map  $f : (\mathcal{PT}_n, *_a) \to (\mathcal{PT}_n, *_b)$  such that  $f(x) = \pi^{-1}x\tau^{-1}$  defines isomorphism between  $(\mathcal{PT}_n, *_a)$  and  $(\mathcal{PT}_n, *_b)$ . In fact f is

bijective and

$$f(x *_a y) = \pi^{-1}x *_a y\tau^{-1} = \pi^{-1}x\tau^{-1}\tau a\pi\pi^{-1}y\tau^{-1} = \pi^{-1}x\tau^{-1}b\pi^{-1}y\tau^{-1} = f(x) *_b f(y).$$

Corollary 1. Let p(k) denote the number of ways in which one can split positive integer k into non ordered sum of the natural integers. Then there are  $\sum_{k=0}^{n} p(k)$  pairwise non-isomorphic semigroups obtained from  $\mathcal{PT}_n$  by the deformed multiplication.
