

CONGRUENCE SUBGROUPS AND THE ATIYAH CONJECTURE

DANIEL R. FARKAS AND PETER A. LINNELL

ABSTRACT. Let $\overline{\mathbb{Q}}$ denote the algebraic closure of \mathbb{Q} in \mathbb{C} . Suppose G is a torsion-free group which contains a congruence subgroup as a normal subgroup of finite index and denote by $\mathcal{U}(G)$ the \mathbb{C} -algebra of closed densely defined unbounded operators affiliated to the group von Neumann algebra of G . We prove that there exists a division ring $D(G)$ such that $\overline{\mathbb{Q}}[G] \subseteq D(G) \subseteq \mathcal{U}(G)$. This establishes some versions of the Atiyah conjecture for the group G .

1. INTRODUCTION

Let p be a prime and let d, i be positive integers. Throughout this paper, \mathbb{Z}_p denotes the p -adic integers, $M_d(R)$ denotes the $d \times d$ matrices over a ring R , and $\text{CS}(i, d, p)$ denotes the congruence subgroup

$$\{A \in M_d(\mathbb{Z}_p) \mid A \equiv I_d \pmod{p^i}\}.$$

(Here I_d is the identity $d \times d$ matrix.) We will *always* assume that $i \geq 2$ whenever the prime p is 2.

We use Passman's notation $R[G]$ for the group ring of G with coefficients in the ring R . Let $\mathcal{U}(G)$ denote the unbounded linear operators affiliated to the group von Neumann algebra of G . A brief description of this object is found at the end of this introduction. The main result of this paper is

Theorem 1.1. *Let d, u be positive integers, let p be a prime, and let G be a torsion-free group which contains a normal subgroup of finite index isomorphic to $\text{CS}(u, d, p)$. Then there is a division ring $D(G)$ such that $\overline{\mathbb{Q}}[G] \subseteq D(G) \subseteq \mathcal{U}(G)$.*

Some years ago, we wrote in [6] an exposition of Moody's and Lazard's contributions to the zero divisor problem. While the first result has been discussed and exploited extensively in the literature, Lazard's observation in [7], that the group ring of a congruence subgroup over the integers is a domain, has not had nearly as much traction. Despite our best efforts, this theorem still has a reputation of being intricate and difficult. Lazard's work focuses on an associated graded ring constructed from finite slices of a congruence subgroup. In this note, we highlight the idea that one can detect whether an element of the group ring is a zero divisor by studying properties of its images in the group rings of various finite quotient groups. A direct approach is possible due to the very clear discussion of filtrations in characteristic p from [10, Chapter 3]. (Don Passman's magnum opus was affectionately referred to as *The Group Algebraist's Guide to the Galaxy* at the conference celebrating his achievements.)

Key words and phrases. Atiyah conjecture, congruence subgroup, zero divisor conjecture, group von Neumann algebra, pro- p group.

For the remainder of the paper, fix positive integers u and d as well as a prime p . Set $\Gamma = \text{CS}(u, d, p)$. Again, we assume that $u \geq 2$ whenever $p = 2$. (This technical point ensures, among other things, that Γ is torsion-free.) We begin with a purely expository presentation of

Theorem 1.2. *If k is a field of characteristic p then $k[\Gamma]$ is a domain.*

It does not appear that the theorem in this generality can be obtained immediately from [7]. Perhaps it is folklore. In any event we can now pass to the case of arbitrary fields of characteristic zero by the following well-known observation: if p is a fixed prime and G is a group with the property that $k[G]$ is a domain for all fields k of characteristic p , then $K[G]$ is a domain for all fields K of characteristic 0. One can obtain this from [10, p. 617] and [10, Exercises 20 and 21]. Thus we have

Theorem 1.3. *If K is a field of characteristic 0 then $K[\Gamma]$ is a domain.*

We shall use the techniques employed in Theorem 1.2 to prove a version of the Atiyah conjecture [9, §10]. Let G be an arbitrary group and write

$$L^2(G) = \left\{ \sum_{g \in G} a_g g \mid a_g \in \mathbb{C} \text{ and } \sum_{g \in G} |a_g|^2 < \infty \right\}.$$

The usual convolution product on $\mathbb{C}[G]$ extends to a module action $\mathbb{C}[G] \times L^2(G) \rightarrow L^2(G)$. Specifically, if $\alpha = \sum_{g \in G} a_g g$ and $\beta = \sum_{g \in G} b_g g$, where $a_g = 0$ for all but finitely many g , then

$$\alpha\beta = \sum_{g \in G} \left(\sum_{h \in G} a_{gh^{-1}} b_h \right) g.$$

Let $\mathcal{B}(L^2(G))$ denote the bounded linear operators on $L^2(G)$. We may view elements of $\mathbb{C}[G]$ as bounded linear operators acting by left multiplication on $L^2(G)$. The group von Neumann algebra $\mathcal{N}(G)$ is the weak closure of $\mathbb{C}[G]$ in $\mathcal{B}(L^2(G))$. Let $\mathcal{U}(G)$ denote the ring of unbounded operators affiliated to the group von Neumann algebra [9, §8.1]. Then we have the following inclusions [8, (8.1), p. 224]:

$$\mathbb{C}[G] \subseteq \mathcal{N}(G) \subseteq L^2(G) \subseteq \mathcal{U}(G).$$

The relevant operations are, of course, compatible. One version of the Atiyah conjecture states that if G is a torsion-free group, then there exists a division ring D such that $\mathbb{C}[G] \subseteq D \subseteq \mathcal{U}(G)$. Although we cannot prove this for virtual congruence subgroups, we do obtain a rational analogue.

2. BACKGROUND

As might be expected in a tribute to Don Passman, we use nontrivial techniques from both group theory and ring theory. We also require heavy doses of topology and analysis.

The exposition begins with rings. Given a ring R , we say a sequence of ideals $R = I_0, I_1, I_2, \dots$ is *descending* provided that

$$I_0 \supseteq I_1 \supseteq I_2 \supseteq \dots$$

and $\bigcap_t I_t = 0$. It is a *descending filtration* if, in addition, it satisfies $I_s I_t \subseteq I_{s+t}$ for all s and t . In this situation, the associated graded ring is

$$\text{gr}(R) = \bigoplus_{j=0}^{\infty} I_j / I_{j+1}.$$

If $r \in I_s \setminus I_{s+1}$ then its image in $\text{gr}(R)$ is the *bottom symbol* of r and we refer to s as the degree of r . For any group G and any field k , the augmentation ideal in the group ring $k[G]$ is denoted $\omega(G)$. We adopt the convention that $\omega(G)^0 = k[G]$. If k is a field of prime characteristic p and G is a finite p -group then the powers of $\omega(G)$ constitute a descending filtration of $k[G]$. This entire paper can be regarded as an obsession with this filtration.

Next, we review some notation for groups. For subgroups A and B , we write $[A, B] = \langle aba^{-1}b^{-1} \mid a \in A, b \in B \rangle$, the commutator group of A and B . For a non-negative integer r , we let $A^r = \langle a^r \mid a \in A \rangle$.

We remind the reader of the fundamental properties of congruence subgroups. Clearly

$$\text{CS}(j, d, p) / \text{CS}(j+1, d, p) \simeq \text{M}_d(\mathbb{Z}/p\mathbb{Z}),$$

the group of matrices under addition. As a consequence, the factor group is an elementary abelian p -group of rank d^2 for all j . For the remainder of the paper we set $e = d^2$. An easy application of the binomial theorem shows that the p -power map induces an isomorphism

$$\text{CS}(j, d, p) / \text{CS}(j+1, d, p) \rightarrow \text{CS}(j+1, d, p) / \text{CS}(j+2, d, p).$$

By using a variant of Hensel's Lemma, one proves that every element of $\text{CS}(j+1, d, p)$ is the p^{th} power of an element in $\text{CS}(j, d, p)$ (see [4, Lemma 5.1]). It follows that

$$\text{CS}(j+1, d, p) = [\text{CS}(j, d, p), \text{CS}(j, d, p)] \text{CS}(j, d, p)^p.$$

If $t > j$, this equality implies that $\text{CS}(j+1, d, p) / \text{CS}(t, d, p)$ is the Frattini subgroup of $\text{CS}(j, d, p) / \text{CS}(t, d, p)$. In particular, if we pull back e "basis" generators of $\text{CS}(j, d, p) / \text{CS}(j+1, d, p)$ to $\text{CS}(j, d, p)$ then the images of these elements generate $\text{CS}(j, d, p) / \text{CS}(t, d, p)$.

Finally, if p is any prime, a direct calculation shows

$$[\text{CS}(i, d, p), \text{CS}(j, d, p)] \subseteq \text{CS}(i+j, d, p)$$

for all positive i, j .

We have already introduced the simplified notation $\Gamma = \text{CS}(u, d, p)$. In this spirit, we set

$$\Gamma_i = \text{CS}(u+i-1, d, p)$$

for all positive integers i . The next lemma summarizes our discussion.

- Lemma 2.1.** (a) Γ_i is characteristic in $\Gamma_1 = \Gamma$ for all i and $\bigcap_i \Gamma_i = 1$.
 (b) $[\Gamma_i, \Gamma_j] \subseteq \Gamma_{i+j}$ for all i, j . Even better, if $p = 2$ then $[\Gamma_i, \Gamma_j] \subseteq \Gamma_{i+j+1}$.
 (c) Γ_i / Γ_{i+1} is an elementary abelian p -group of rank $e = d^2$ and the p -power map induces an isomorphism from Γ_i / Γ_{i+1} to $\Gamma_{i+1} / \Gamma_{i+2}$ for all i .
 (d) For all i , each element of Γ_{i+1} is the p^{th} power of an element in Γ_i .
 (e) There are elements $y_1, \dots, y_e \in \Gamma$ such that $y_1 \Gamma_t, \dots, y_e \Gamma_t$ generate Γ / Γ_t for all t .

3. THE ASSOCIATED GRADED RING

There is nothing mathematically new in this section. The intended contribution is clarity; without recasting the original argument, we would not have made progress on the Atiyah conjecture.

Recall the notion of an N_p -sequence for a group G , as described in [10, §3.3]. It is a sequence of normal subgroups

$$G = H_1 \supseteq H_2 \supseteq H_3 \supseteq \cdots$$

such that $[H_i, H_j] \subseteq H_{i+j}$ and $H_i^p \subseteq H_{ip}$ for all i, j . Our first step is to renumber the sequence of congruence subgroups in Lemma 2.1 so that it becomes an N_p -sequence for Γ . Indeed, simply set $\Gamma_i^* = \Gamma_{\lceil \log_p i \rceil + 1}$, where $\lceil x \rceil$ indicates the least integer greater than or equal to x . Then $\Gamma_1^* = \Gamma_1$ (which we also write Γ^*), $\Gamma_2^* = \Gamma_2$, \dots , $\Gamma_p^* = \Gamma_2$, $\Gamma_{p+1}^* = \Gamma_3$, \dots . The new sequence has many successive repeats; the only jumps can occur between $\Gamma_{p^i}^*$ and $\Gamma_{p^{i+1}}^*$.

Lemma 3.1. *Let Γ_i^* be defined as above. Then $\{\Gamma_i^*\}$ is an N_p -sequence for Γ .*

Proof. Since $(\lceil \log_p i \rceil + 1) + (\lceil \log_p j \rceil + 1) \geq \lceil \log_p(i+j) \rceil + 1$, it follows from Lemma 2.1(b) that $[\Gamma_i^*, \Gamma_j^*] \subseteq \Gamma_{i+j}^*$. Furthermore, Lemma 2.1(c) and $\lceil \log_p ip \rceil + 1 = \lceil \log_p i \rceil + 2$ imply $(\Gamma_i^*)^p \subseteq \Gamma_{ip}^*$. \square

Let t be a positive integer, and set $\Gamma^\otimes = \Gamma/\Gamma_t$, a finite group of order $p^{(t-1)e}$. The homomorphic images $\Gamma_i^\otimes = \Gamma_i^*/\Gamma_t$ for $t \geq \lceil \log_p i \rceil$ constitute an N_p -sequence for Γ^\otimes . Let $x_1, \dots, x_e \in \Gamma^\otimes$ denote the generators $y_1\Gamma_t, \dots, y_e\Gamma_t$ from Lemma 2.1(e). (These elements make up a ‘‘basis’’ for $\Gamma^\otimes/\Gamma_2^\otimes$.) We apply Passman’s exposition of [10, §3.3] to the finite group Γ^\otimes . For $g \in \Gamma^\otimes$, he defines the height $\nu(g)$ to be the greatest positive integer n such that $g \in \Gamma_n^\otimes$. By agreement, $\nu(1) = \infty$.

Once and for all, *assume that k is a field of characteristic p .*

Next, Passman defines $E_i \subseteq k[\Gamma^\otimes]$ to be the k -linear span of all products of the form

$$(g_1 - 1)(g_2 - 1) \cdots (g_n - 1)$$

with $\nu(g_1) + \nu(g_2) + \cdots + \nu(g_n) \geq i$. It is clear that E_i is an ideal of $k[\Gamma^\otimes]$ for all i and we have a descending filtration

$$k[\Gamma^\otimes] = E_0 \supseteq E_1 \supseteq E_2 \supseteq \cdots$$

At this point, Passman refines the series $\{\Gamma_i^\otimes\}$, obtaining a composition series. (One caveat: the new series does not have repeated terms even though the original series does.) He constructs a sequence of elements in Γ^\otimes by choosing, in order, a preimage for each generator of a composition factor. Because of Lemma 2.1(c), we may choose the sequence as

$$x_1, \dots, x_e, x_1^p, \dots, x_e^p, \dots, x_1^{p^{t-2}}, \dots, x_e^{p^{t-2}}.$$

Notice that we have $\nu(x_i^{p^s}) = p^s$. According to [10, Lemma 3.3.5], the products

$$(x_1 - 1)^{b(1,1)}(x_2 - 1)^{b(2,1)} \cdots (x_{e-1}^{p^{t-2}} - 1)^{b(e-1,t-1)}(x_e^{p^{t-2}} - 1)^{b(e,t-1)}$$

with

$$0 \leq b(m,n) < p \text{ for all } m, n \text{ and } \sum_{i=1}^e \sum_{j=0}^{t-2} p^j b(i, j+1) \geq s$$

constitute a basis for E_s .

We show that the associated graded ring $\text{gr}(k[\Gamma^\otimes])$ is commutative. Since $(x_i - 1)^{p^j} = x_i^{p^j} - 1$, it is sufficient to show that $x_i - 1$ and $x_j - 1$ commute in $\text{gr}(k[\Gamma^\otimes])$, or equivalently, $(x_i - 1)(x_j - 1) - (x_j - 1)(x_i - 1) \in E_3$. Now $(x_i - 1)(x_j - 1) - (x_j - 1)(x_i - 1) = (1 - [x_i, x_j])x_i x_j$, so we need to prove $1 - [x_i, x_j] \in E_3$, i.e.,

$[\Gamma, \Gamma] \subseteq \Gamma_3^*$. This can be read off of Lemma 2.1(b), with a bit of care paid to the prime 2. We have established that the graded ring is commutative.

The upshot of the argument so far is that E_s has a better basis, namely all products

$$(x_1 - 1)^{a(1)}(x_2 - 1)^{a(2)} \dots (x_e - 1)^{a(e)}$$

subject to $a(j) < p^{t-1}$ for all j and $\sum_{j=1}^e a(j) \geq s$. Obviously $E_s \subseteq \omega(\Gamma^{\otimes})^s$. On the other hand $\Gamma^{\otimes} = \langle x_1, \dots, x_e \rangle$, whence $\omega(\Gamma^{\otimes}) = E_1$. Using the new basis and the commutativity of $\text{gr}(k\Gamma^{\otimes})$, we deduce that $E_s = \omega(\Gamma^{\otimes})^s$ for all $s \in \mathbb{Z}_{\geq 0}$.

A quick glance at the exponent restrictions in the previous paragraph establishes the following consequence upon which Lazard's strategy rests.

Lemma 3.2. *Let $\Gamma^{\otimes} = \Gamma/\Gamma_t$ as above. Then the associated graded ring $\text{gr}(k[\Gamma^{\otimes}]) = \bigoplus_{i \geq 0} \omega(\Gamma^{\otimes})^i / \omega(\Gamma^{\otimes})^{i+1}$ is isomorphic to a polynomial ring in e indeterminates modulo degree p^{t-1} or greater.*

On a parenthetical note, recall that the n^{th} dimension subgroup for a group G at the prime p is

$$D_n(G) = \{g \in G \mid g - 1 \in \omega(G)^n\}.$$

(Here the augmentation ideal is taken inside $k[G]$ for a field k of characteristic p .) Observe that by definition, if $y \in \Gamma_n^{\otimes}$ then $y - 1 \in E_n$. Since we have just proved that $E_n = \omega(\Gamma^{\otimes})^n$, we see that $\Gamma_n^{\otimes} \subseteq D_n(\Gamma^{\otimes})$. But $D_n(\Gamma^{\otimes})$ is the smallest N_p -sequence of Γ^{\otimes} [10, Theorem 3.3.7]. Therefore $\Gamma_n^{\otimes} = D_n(\Gamma^{\otimes})$. It is not difficult to make the jump and conclude that Γ_n^* is the n^{th} dimension subgroup for Γ^* .

Lemma 3.3. $\omega(\Gamma)^{(p^{t-1}e-e+1)} \subseteq \omega(\Gamma_t)k[\Gamma] \subseteq \omega(\Gamma)^{p^{t-1}}$ for all t .

Proof. We work inside $\Gamma^{\otimes} = \Gamma/\Gamma_t$ and first show that $\omega(\Gamma^{\otimes})^{(p^{t-1}e-e+1)}$ is the zero ideal. Recall that this ideal has a basis

$$(x_1 - 1)^{a(1)}(x_2 - 1)^{a(2)} \dots (x_e - 1)^{a(e)}$$

subject to $a(j) \leq p^{t-1} - 1$ and $\sum_{j=1}^e a(j) \geq p^{t-1}e - e + 1$. Since there are no such $a(j)$, the basis is empty, i.e., the requisite ideal is zero.

As to the second inclusion, Lemma 2.1(d) implies that each element of Γ_t has the form $y^{p^{t-1}}$ for some $y \in \Gamma$. Hence $\omega(\Gamma_t)$ is spanned by all $y^{p^{t-1}} - 1 = (y-1)^{p^{t-1}}$ as y ranges over Γ . \square

From this we deduce Theorem 1.2.

Corollary 3.4. *The associated graded ring $\text{gr}(k[\Gamma]) = \bigoplus_{i=0}^{\infty} \omega(\Gamma)^i / \omega(\Gamma)^{i+1}$ is isomorphic to the polynomial ring in e variables. Furthermore $\bigcap \omega(\Gamma)^i = 0$ and consequently $k[\Gamma]$ is a domain.*

Proof. Initially fix t and consider $\Gamma^{\otimes} = \Gamma/\Gamma_t$. According to Lemma 3.3, $\omega(\Gamma_t) \subseteq \omega(\Gamma)^{p^{t-1}}$. It follows that the kernel of the map from $\omega(\Gamma)^i$ to $\omega(\Gamma^{\otimes})^i$ coincides with the kernel of the natural map from $k[\Gamma]$ to $k[\Gamma^{\otimes}]$ whenever $i \leq p^{t-1}$. Therefore $\text{gr}(k[\Gamma])$ and $\text{gr}(k[\Gamma^{\otimes}])$ are isomorphic modulo degree p^{t-1} . Apply Lemma 3.2 and let t tend to infinity to obtain the isomorphism of graded rings.

To see that $k[\Gamma]$ is a domain, we now need only check that

$$\bigcap_i \omega(\Gamma)^i = 0.$$

Since $\bigcap_j \Gamma_j = 1$, every nonzero element a of $k[\Gamma]$ survives in $k[\Gamma/\Gamma_t]$ for large enough t . That is, $a \notin \omega(\Gamma_t)k[\Gamma]$ for some t . By Lemma 3.3, $a \notin \bigcap_i \omega(\Gamma)^i$ \square

4. COMPLETED GROUP RINGS

The main result in this section, Theorem 4.3(b), appears as [13, Theorem 8.7.10] and a special case of [2, Theorem C] when the field k is finite. Recall that for us, k is any field of characteristic p .

Let R be a ring with a descending sequence I_0, I_1, I_2, \dots of ideals. The *completion* of R is

$$\overline{R} = \varprojlim R/I_j.$$

In this section, we assume that each R/I_j has the discrete topology. However, \overline{R} has the usual inverse limit topology that makes it into a Hausdorff topological ring. (This is an example of a linear topology on R .) There is a more prosaic description of \overline{R} under this set-up that the reader may find useful. Define a sequence r_1, r_2, r_3, \dots in R to be Cauchy provided that for every $s \geq 0$ there exists $N \geq 0$ such that $r_i - r_j \in I_s$ for all $i, j \geq N$. Then \overline{R} is the ring of all Cauchy sequences modulo the usual equivalence relation used in advanced calculus. For a neighborhood base at zero, we may take all closures $\overline{I_j}$.

From this description, it is clear that if J_0, J_1, J_2, \dots is a second descending sequence for R and if for all m, n there exist m', n' with

$$I_m \supseteq J_{m'} \text{ and } J_n \supseteq I_{n'}$$

then the two completed rings are isomorphic via a homeomorphism. For example, Lemma 3.3 tells us that the completions of $k[\Gamma]$ given by the descending sequences

$$k[\Gamma] \supseteq \omega(\Gamma_1)k[\Gamma] \supseteq \omega(\Gamma_2)k[\Gamma] \supseteq \dots \text{ and}$$

$$k[\Gamma] \supseteq \omega(\Gamma) \supseteq \omega(\Gamma)^2 \supseteq \omega(\Gamma)^3 \supseteq \dots$$

are the same. We denote this common completion by $k[[\Gamma]]$.

We will need several easy exercises whose proofs are left to the reader.

Lemma 4.1. *Assume $R = I_0 \supseteq I_1 \supseteq I_2 \supseteq \dots$ is a descending sequence of ideals for R .*

(a) *The canonical homomorphism $R \rightarrow \overline{R}$ induces an isomorphism*

$$R/I_t \rightarrow \overline{R}/\overline{I_t}$$

for each t .

(b) $\bigcap_s \overline{I_s} = 0$.

The following lemma is undoubtedly well known to experts in topological rings but has not been exploited in our context.

Lemma 4.2. *Assume that F is a commutative ring. Let \overline{R} be the completion of the F -algebra R with respect to a descending filtration of ideals*

$$R = I_0 \supseteq I_1 \supseteq I_2 \supseteq \dots$$

in which R/I_s is an artinian F -algebra for all s . Then finitely generated left (right) ideals of \overline{R} are closed.

Remark. In the case F is a field, the hypothesis that R/I_s is an artinian F -algebra is the same as I_s having finite codimension in R .

Proof of Lemma 4.2. We take advantage of the theory of linearly compact modules over a Hausdorff linearly topological ring. (A detailed discussion of this topic can be found in [12, Chapter VII].)

We consider R/I_n as a left (or right) \overline{R} -module by Lemma 4.1. Since R/I_n is artinian over F , it is linearly compact [12, 28.14]. According to the argument in [12, 28.15] (essentially Tychonoff's theorem), the inverse limit of linearly compact modules is linearly compact. Hence \overline{R} is linearly compact as a module over itself.

If $a \in \overline{R}$ then \overline{Ra} is linearly compact because it is the continuous homomorphic image of a linearly compact \overline{R} -module [12, 28.3]. It follows that \overline{Ra} is closed in \overline{R} [12, 28.6(2)]. Finally, the sum of two closed submodules of a linearly compact module is closed [12, 28.6(3)]. We conclude that any finitely generated left ideal of \overline{R} is closed. \square

The streamlined notation $\overline{\omega}(\Gamma)$ will be used for the closure of the augmentation ideal in $k[[\Gamma]]$.

Theorem 4.3. (a) *The associated graded ring $\text{gr}(k[[\Gamma]]) = \bigoplus_{i=0}^{\infty} \overline{\omega}(\Gamma)^i / \overline{\omega}(\Gamma)^{i+1}$ is isomorphic to the polynomial ring in e variables.*

(b) *The completed group ring $k[[\Gamma]]$ is a noetherian domain.*

Proof. Recall that $\bigcap_j \omega(\Gamma)^j = 0$ by Corollary 3.4. It then follows from Lemma 4.1 that the powers of $\overline{\omega}(\Gamma)$ make up a descending filtration for $k[[\Gamma]]$ with

$$\text{gr } k[[\Gamma]] \simeq \text{gr } k[\Gamma].$$

Part (a) now follows from Corollary 3.4. Furthermore, since $\text{gr } k[[\Gamma]]$ is a domain, we conclude that the completion $k[[\Gamma]]$ is, too.

To see that $k[[\Gamma]]$ is (left) noetherian, consider a nonzero left ideal L . The collection of its bottom symbols in $\text{gr } k[[\Gamma]]$ constitute a homogeneous left ideal, $\text{gr } L$, inside the graded algebra. But $\text{gr } k[[\Gamma]]$ is isomorphic to a polynomial ring in e indeterminates and thus is noetherian. Choose finitely many homogeneous generators for $\text{gr } L$ and lift them to elements b_1, b_2, \dots, b_m in L . Suppose $y \in L$ is nonzero and has degree s . We peel off the bottom of y : there exist $r_1, \dots, r_m \in k[[\Gamma]]$ such that the bottom symbol of

$$y - r_1 b_1 - \dots - r_m b_m$$

has degree greater than s . Continuing inductively in this fashion, we see that y lies in the closure of the left ideal generated by b_1, \dots, b_m . However, this ideal is already closed (apply Lemma 4.2 with $F = k$). Therefore L itself is finitely generated. \square

5. A KEY ESTIMATE

Our goal for the rest of the paper is to settle the Atiyah problem for virtual congruence subgroups. The strategy is to establish the algebraic ingredient in Lück's approach: an approximate nullity of matrices over the group algebra always takes on integer values. We accomplish this in a series of steps. In this section, we address the "one-dimensional case" for $k[[\Gamma]]$. The next step is to extend this estimate "up by finite index". At the end, we apply gaussian elimination to reduce the matrix computation to the scalar case.

We continue using the notation $\Gamma_i = \text{CS}(u + i - 1, d, p)$ with $\Gamma = \Gamma_1$. As usual, k is a field of characteristic p .

Lemma 5.1. *Fix a positive integer m and let $\pi: k[[\Gamma]] \rightarrow k[\Gamma]/\omega(\Gamma)^m$ be the canonical homomorphism. Assume $0 \neq a \in k[[\Gamma]]$ has degree s where $m > s$. Denote by $L: \pi(k[[\Gamma]]) \rightarrow \pi(k[[\Gamma]])$ the map “multiply on the left by $\pi(a)$ ”. Then*

$$\ker L = \pi(\overline{\omega}(\Gamma)^{m-s}).$$

Proof. Since $a \in \pi(\overline{\omega}(\Gamma)^s)$, we have

$$\pi(\overline{\omega}(\Gamma)^{m-s}) \subseteq \ker L.$$

On the other hand, suppose $0 \neq b \in k[[\Gamma]]$ with $\pi(b) \in \ker L$. Let t be the degree of b . According to Theorem 4.3(a), $ab \notin \overline{\omega}^{s+t+1}$. But $\pi(ab) = 0$, so $ab \in \overline{\omega}(\Gamma)^m$. Thus $s + t + 1 > m$. In other words, $t \geq m - s$. Therefore

$$\pi(b) \in \pi(\overline{\omega}(\Gamma)^t) \subseteq \pi(\overline{\omega}(\Gamma)^{m-s}).$$

□

Recall that there is a ring homomorphism $k[[\Gamma]] \rightarrow k[\Gamma/\Gamma_n]$ for all positive integers n by Lemma 4.1. Use the notation $[\Gamma: \Gamma_n] = |\Gamma/\Gamma_n|$.

Lemma 5.2. *Fix $0 \neq a \in k[[\Gamma]]$ and for each $n \geq 1$ let $\alpha_n: k[\Gamma/\Gamma_n] \rightarrow k[\Gamma/\Gamma_n]$ denote the map induced from left multiplication by a in $k[[\Gamma]]$. Then*

$$\lim_{n \rightarrow \infty} (\dim_k \ker \alpha_n) / [\Gamma: \Gamma_n] = 0.$$

Proof. Initially fix n and set $m = p^{n-1}e - e + 1$. By Lemma 3.3, $\omega(\Gamma)^m \subseteq \omega(\Gamma_n)k[\Gamma]$. Hence there is a natural right $k[[\Gamma]]$ -module surjection $k[\Gamma]/\omega(\Gamma)^m \rightarrow k[\Gamma]/\omega(\Gamma_n)k[\Gamma]$. Let

$$L_n: k[\Gamma]/\omega(\Gamma)^m \rightarrow k[\Gamma]/\omega(\Gamma)^m$$

be the map induced from left multiplication by a . Since this multiplication map is a right $k[[\Gamma]]$ -module map,

$$\dim_k \ker L_n = \dim_k \operatorname{coker} L_n \geq \dim_k \operatorname{coker} \alpha_n = \dim_k \ker \alpha_n.$$

Thus it will be sufficient to show that $\lim_{n \rightarrow \infty} (\dim_k \ker L_n) / [\Gamma: \Gamma_n] = 0$.

Let s be the degree of a in $k[[\Gamma]]$. Lemma 5.1 established that

$$\dim_k \ker L_n = \dim_k (\omega(\Gamma)^{m-s} / \omega(\Gamma)^m).$$

This number is the same as the number of monomials in the polynomial ring with e variables each of which has total degree in the interval $[m-s, m)$. It is well known that the number of monomials of degree less than r is $\binom{e+r-1}{e}$. Hence

$$\dim_k \ker L_n = \binom{e+m-1}{e} - \binom{e+m-s-1}{e}.$$

As a polynomial in m , each binomial coefficient has leading term m^e . Their difference is a polynomial in m with degree at most $e-1$. Thus there is a constant C (independent of m) such that

$$\dim_k \ker L_n \leq C(m+e-1)^{e-1}.$$

Now $[\Gamma: \Gamma_n] = p^{e(n-1)}$. Therefore

$$\frac{\dim_k \ker L_n}{[\Gamma: \Gamma_n]} \leq C(p^{n-1}e)^{e-1} p^{-e(n-1)} = \frac{C e^{e-1}}{p^{n-1}}.$$

Take the limit as n tends to ∞ . □

6. VIRTUAL CONGRUENCE SUBGROUPS

Henceforth, we will reserve the symbol G for a torsion-free group that contains a normal subgroup of finite index isomorphic to Γ . By abuse of notation, we identify this subgroup with Γ .

Theorem 6.1. *$k[[G]]$ is a right and left noetherian domain.*

Proof. Clearly G is a profinite group, and since it is torsion-free, it is easy to see from [13, Proposition 2.3.3] that G is a pro- p group. A version of the construction discussed in Section 4 makes it legitimate to write $k[[G]]$.

We know by Theorem 4.3(b) that $k[[\Gamma]]$ is a noetherian domain. Let S denote the nonzero elements of $k[[\Gamma]]$. Then S is a right Ore set in $k[[\Gamma]]$ that does not contain zero divisors. This means the ring of fractions $k[[\Gamma]]S^{-1}$ is a division ring. This ring consists of elements of the form as^{-1} with $a \in k[[\Gamma]]$ and $s \in S$; however because $k[[\Gamma]]$ is left noetherian, it also consists of elements of the form $s^{-1}a$ with $a \in k[[\Gamma]]$ and $s \in S$. By [13, Proposition 7.6.3], $k[[G]]$ is a free right $k[[\Gamma]]$ -module with basis any (left) transversal for Γ in G . Since G/Γ is finite, we see that $k[[G]]$ is a free right $k[[\Gamma]]$ -module in the usual module theoretic sense. It now follows that $k[[G]]$ is noetherian and that S is also a right Ore set in $k[[G]]$, so we can form the ring $k[[G]]S^{-1}$. This will be an Artinian ring and a right $k[[\Gamma]]S^{-1}$ -module containing $k[[G]]$.

We know by [13, Proposition 8.5.1] that Γ is a pro- p group of finite rank. Therefore by [13, Proposition 8.1.1], G is a profinite group of finite rank; we deduce from [13, Theorem 11.6.9] that G has finite cohomological dimension. It now follows from the results of [3] that $k[[G]]$ has finite global dimension. In fact, on [3, p. 443] of Brumer's paper, one finds that if G is a pro- p group of finite cohomological dimension and Ω is a complete regular local ring in which p is not a unit then $\Omega[[G]]$ is a complete noncommutative local ring of finite global dimension. We apply this with $k = \Omega$.

Suppose $k[[G]]S^{-1}$ is not a division ring. We borrow the strategy of using Walker's Theorem [11] as first introduced by Ken Brown [1]. There must be an ideal I of $k[[G]]S^{-1}$ such that $0 < \dim_{k[[\Gamma]]S^{-1}} I < [G : \Gamma]$. Set $J = k[[G]] \cap I$, so I is a right ideal of $k[[G]]$ and $JS^{-1} = I$. Since $k[[G]]$ is a right noetherian ring with finite cohomological dimension, there is a resolution

$$0 \longrightarrow P_n \longrightarrow P_{n-1} \longrightarrow \dots \longrightarrow P_0 \longrightarrow J \longrightarrow 0$$

where the P_i are finitely generated projective $k[[G]]$ -modules. By [13, Corollary 7.5.4], each P_i is a free $k[[G]]$ -module, and since P_i is finitely generated, this simply means that P_i is free in the usual module theoretic sense. Applying S^{-1} to the resolution of J , we obtain a resolution of JS^{-1} with free $k[[G]]S^{-1}$ -modules. We deduce that $\dim_{k[[\Gamma]]S^{-1}} JS^{-1}$ is a multiple of $[G : \Gamma]$. This is a contradiction. \square

Suppose that R is a complete discrete valuation ring with maximal ideal qR . Assume, in addition, that R/qR is a field of characteristic p . We regard R as a Hausdorff topological ring as in Section 4 by assuming that each R/q^jR has the discrete topology and then giving R the inverse limit topology. Now define $R[[G]] = \varprojlim R[G/N]$, where the inverse limit is taken over the open normal subgroups N of G . (Here each $R[G/N]$ is given the product topology of a finitely generated free R -module.) By construction, $\bigcap_n q^n R[[G]] = 0$. It is also easy to see that nonzero members of R cannot become zero divisors in $R[[G]]$.

Corollary 6.2. *Let R be a complete discrete valuation ring with maximal ideal qR such that R/qR is a field of characteristic p . Then $R[[G]]$ is a domain.*

Proof. Set $k = R/qR$. There is a continuous surjective ring homomorphism

$$\theta: R[[G]] \rightarrow k[[G]]$$

with kernel $qR[[G]]$. Suppose $0 \neq a, c \in R[[G]]$. Write

$$a = q^m \tilde{a} \quad \text{and} \quad c = q^n \tilde{c}$$

with $\tilde{a}, \tilde{c} \notin qRG$. Then

$$\theta(\tilde{a}\tilde{c}) = \theta(\tilde{a})\theta(\tilde{c}) \neq 0$$

by Theorem 6.1. We conclude that $\tilde{a}\tilde{c} \neq 0$, so $ac \neq 0$. \square

Since Γ_n is characteristic in Γ , each of these subgroups is normal in G . It follows from [13, Proposition 7.1.2(c)] that there is a homomorphism $k[[G]] \rightarrow k[[G/\Gamma_n]]$ for all n . In particular, left multiplication by an element of $k[[G]]$ induces a right module endomorphism of $k[G/\Gamma_n]$ for each n .

Lemma 6.3. *Suppose $a \in k[[G]]$ is nonzero and $\alpha_n: k[G/\Gamma_n] \rightarrow k[G/\Gamma_n]$ denotes the map induced from left multiplication by a in $k[[G]]$. Then*

$$\lim_{n \rightarrow \infty} (\dim_k \ker \alpha_n) / [G: \Gamma_n] = 0.$$

Proof. By Theorem 6.1, $k[[G]]$ is a domain and $k[[\Gamma]]$ is a noetherian Ore domain inside. As we have already observed in the proof of Theorem 6.1, if $S = k[[\Gamma]] \setminus 0$ then we may form the division ring of fractions $S^{-1}k[[G]]$. This means that we can find $b \in k[[G]]$ such that $0 \neq ba \in k[[\Gamma]]$. For each non-negative integer n , let $\sigma_n: k[G/\Gamma_n] \rightarrow k[G/\Gamma_n]$ denote the right $k[G/\Gamma_n]$ -map induced from left multiplication by ba on $k[[G]]$. Similarly, let $\sigma_n|: k[\Gamma/\Gamma_n] \rightarrow k[\Gamma/\Gamma_n]$ be the corresponding map for the restriction of multiplication by ba to the subalgebra $k[[\Gamma]]$. Clearly

$$\dim_k \ker \sigma_n = [G: \Gamma] \dim_k \ker(\sigma_n|).$$

Since $[G: \Gamma_n] = [G: \Gamma][\Gamma: \Gamma_n]$, Lemma 5.2 implies

$$\lim_{n \rightarrow \infty} (\dim_k \ker \sigma_n) / [G: \Gamma_n] = 0.$$

But $\dim_k \ker \alpha_n \leq \dim_k \ker \sigma_n$. We deduce that the desired limit is zero. \square

For the rest of this paper, we will assume that k is a *finite* field of characteristic p . This choice is mainly made for convenience; we would like to quote Wilson [13], who requires that his completed algebras be profinite. Mathematically, this is primarily an issue of applying compactness rather than linear compactness. We can now state

Proposition 6.4. *Let R be a discrete valuation ring with maximal ideal qR such that R/qR is a finite field of characteristic p . Then $R[[G]]$ is a noetherian domain.*

Proof. According to [13, Propositions 8.1.1, 8.5.1 and Theorem 8.7.8], $R[[G]]$ is noetherian. The result now follows from Corollary 6.2. \square

Remark. Actually Proposition 6.4 remains true if R/qR is an arbitrary field of characteristic p . We sketch the argument for this. We already know that $R[[G]]$ is a domain by Corollary 6.2, so it remains to prove that $R[[G]]$ is noetherian. To establish this, it will be sufficient to descend to a subgroup of finite index in G . We may now assume that G is “extra powerful” [13, p. 148 and Proposition 8.5.2]. Let

Δ denote the unique maximal ideal of $R[[G]]$. Then $\text{gr}(R[[G]]) := \bigoplus_{i=0}^{\infty} \Delta^i / \Delta^{i+1}$ is a commutative noetherian ring by the proofs of [13, Theorems 8.7.6 and 8.7.7]. We can now use Lemma 4.2 and the proof of Theorem 4.3(b) to establish that $R[[G]]$ is noetherian.

Suppose that R is a ring as described in the previous corollary. Since R is a principal ideal domain, any submodule M of a finitely generated free R -module is again free. (During the discussion that follows, the free module will be the ring of all matrices of some size over $R[H]$ for a finite group H .) In particular, M has a well-defined rank, which we perversely write as $\dim_R M$ to conform with earlier notation. Note that if K is the field of fractions for R then

$$\dim_K K \otimes_R M = \dim_R M.$$

Corollary 6.5. *Let R be a complete discrete valuation ring with maximal ideal qR such that R/qR is a finite field of characteristic p . Suppose $a \in R[[G]]$ is nonzero and $\alpha_n: R[G/\Gamma_n] \rightarrow R[G/\Gamma_n]$ denotes the map induced from left multiplication by a in $R[[G]]$. Then*

$$\lim_{n \rightarrow \infty} (\dim_R \ker \alpha_n) / [G : \Gamma_n] = 0.$$

Proof. Write $a = q^f c$ where the non-negative integer f is chosen so that $c \in R[[G]] \setminus qR[[G]]$. Let $\xi_n: R[G/\Gamma_n] \rightarrow R[G/\Gamma_n]$ be the multiplication map induced from c . If k denotes the residue field for R , we obtain a right $k[G/\Gamma_n]$ -endomorphism by factoring out q ,

$$\xi_n^*: k[G/\Gamma_n] \rightarrow k[G/\Gamma_n].$$

(It is induced from left multiplication by the *nonzero* image of c in $k[[G]]$.)

We may choose an R -basis for $\ker \xi_n$ that consists of elements in $R[G/\Gamma_n] \setminus qR[G/\Gamma_n]$. Their images modulo q remain linearly independent. Hence

$$\dim_R \ker \xi_n \leq \dim_k \ker \xi_n^*.$$

But $\dim_R \ker \alpha_n = \dim_R \ker \xi_n$. The required inequality is now a consequence of Lemma 6.3. \square

7. MATRICES

Lemma 7.1. *Let R be a complete discrete valuation ring with maximal ideal qR such that R/qR is a finite field of characteristic p , and let h be a positive integer. For $A \in M_h(R[[G]])$ and for each positive integer n , let $\mathcal{A}_n: R[G/\Gamma_n]^h \rightarrow R[G/\Gamma_n]^h$ denote the right $R[G/\Gamma_n]$ -module map induced from acting by A on the left. Then $\lim_{n \rightarrow \infty} (\dim_R \ker \mathcal{A}_n) / [G : \Gamma_n]$ is an integer.*

Proof. Since $R[[G]]$ is an Ore domain by Proposition 6.4, it has a division ring of fractions Q . By performing complete row and column reduction, we can find invertible $B, C \in M_h(Q)$ such that BAC is a diagonal matrix D with only zeros and ones on the main diagonal. Let δ denote the number of such zeros in D (so $0 \leq \delta \leq h$). Using the fact that $R[[G]]$ is a left and right Ore domain, we can find nonzero b, c in $R[[G]]$ such that $bB, Cc \in M_h(R[[G]])$. Now $(bB)A(Cc)$ is a diagonal matrix with bc appearing $h - \delta$ times on the diagonal and zero appearing δ times down the diagonal. Let $\alpha_n: R[G/\Gamma_n] \rightarrow R[G/\Gamma_n]$ denote the right $R[G/\Gamma_n]$ -map induced from left multiplication by bc . Similarly, let $\mathcal{B}_n, \mathcal{C}_n: R[G/\Gamma_n]^h \rightarrow R[G/\Gamma_n]^h$ be the module maps induced from the left action of bB and Cc respectively. Then

$$\dim_R \ker \mathcal{A}_n \leq \dim_R \ker (\mathcal{B}_n \mathcal{A}_n \mathcal{C}_n) = (h - \delta) \dim_R \ker \alpha_n + \delta [G : \Gamma_n].$$

But $\lim_{n \rightarrow \infty} \dim_R \ker \alpha_n / [G : \Gamma_n] = 0$ by Corollary 6.5. We conclude that

$$(7.2) \quad \overline{\lim}_{n \rightarrow \infty} (\dim_R \ker \mathcal{A}_n) / [G : \Gamma_n] \leq \delta.$$

Let $E \in M_n(Q)$ denote the diagonal matrix obtained from D by replacing each one with zero and each zero on the diagonal with one. The upshot is that E has $h - \delta$ diagonal zeros and $DE = 0$. Since B is invertible, we deduce that $ACE = 0$. As above, we can find a nonzero x in $R[[G]]$ such that CEx is a matrix X in $M_h(R[[G]])$. Then $AX = 0$ and $C^{-1}Xx^{-1} = E$. Choose a nonzero $c' \in R[[G]]$ so that $c'C^{-1} \in M_h(R[[G]])$. As a consequence, $(c'C^{-1})X$ is a diagonal matrix with $c'x$ appearing δ times on the diagonal and zero appearing $h - \delta$ times down the diagonal. Repeat the argument of the first paragraph replacing A with X . We conclude that if $\mathcal{X}_n : R[G/\Gamma_n]^h \rightarrow R[G/\Gamma_n]^h$ denotes the map induced from the left action of X then

$$\overline{\lim}_{n \rightarrow \infty} (\dim_R \ker \mathcal{X}_n) / [G : \Gamma_n] \leq h - \delta.$$

Therefore $\underline{\lim}_{n \rightarrow \infty} (\dim_R \ker \mathcal{X}_n) / [G : \Gamma_n] \geq \delta$. We conclude from $\mathcal{A}_n \mathcal{X}_n = 0$ that

$$(7.3) \quad \underline{\lim}_{n \rightarrow \infty} (\dim_R \ker \mathcal{A}_n) / [G : \Gamma_n] \geq \delta.$$

Combining (7.2) and (7.3), we deduce that $\lim_{n \rightarrow \infty} (\dim_R \ker \mathcal{A}_n) / [G : \Gamma_n] = \delta$. Of course, δ is by definition an integer. \square

We can finally settle the Atiyah problem for virtual congruence subgroups. The remaining argument essentially explains how the integer limit lemma we have just proved fits into well established work on this problem.

Proof of Theorem 1.1. An arbitrary $\mathcal{N}(G)$ -module M has a well-defined von Neumann dimension $\dim_{\mathcal{N}(G)} M$ [9, §6.1]. According to the proof of [9, Lemma 10.39], it suffices to show that for any $A \in M_h(\overline{\mathbb{Q}}G)$, the induced left action map $\mathcal{A} : L^2(G)^h \rightarrow L^2(G)^h$ satisfies the integrality condition

$$\dim_{\mathcal{N}(G)} \ker \mathcal{A} \in \mathbb{Z}.$$

(Technically, Lück's proof is stated for \mathbb{C} rather than $\overline{\mathbb{Q}}$, but the proof works just as well in this situation.) Since A has only finitely many entries, we may assume that $A \in M_h(K[G])$ for some algebraic number field K . Lück's condition will follow if we can show that

$$\lim_{n \rightarrow \infty} (\dim_K \ker \mathcal{A}_n) / [G : \Gamma_n] \in \mathbb{Z}$$

where $\mathcal{A}_n : K[G/\Gamma_n]^h \rightarrow K[G/\Gamma_n]^h$ is the right module map induced from the left action of A (see [5, Theorem 1.6]).

Extend the p -adic valuation on \mathbb{Q} to K and complete K to obtain \hat{K} . Let R be the complete discrete valuation ring determined by the extended valuation. Choose a nonzero $r \in R$ so that $B = rA$ lies in $M_h(R[G])$. Define \mathcal{B}_n on $R[G/\Gamma_n]^h$ in the usual way from the left action of B . By the remarks preceding Corollary 6.5,

$$\dim_R \ker \mathcal{B}_n = \dim_{\hat{K}} \ker(1 \otimes_{\hat{K}} \mathcal{A}_n) = \dim_K \ker \mathcal{A}_n.$$

Apply Lemma 7.1 to obtain $\lim_{n \rightarrow \infty} \dim_R(\ker \mathcal{B}_n) / [G : \Gamma_n] \in \mathbb{Z}$ and substitute. \square

Finally we remark that the main result of this paper remains true when G is a torsion-free p -adic analytic (or Lie) group [4, Definition 8.14] or, equivalently, a torsion-free pro- p group of finite rank [4, Corollary 8.34]. Such a group has a ‘‘uniform’’ open characteristic subgroup [13, Theorem 8.5.3], which plays the rôle

of our congruence subgroups; in particular one needs to replace Theorem 4.3(a) with [13, Theorem 8.7.10]. For completeness, we state

Theorem 7.4. *Let G be a torsion-free pro- p group of finite rank. Then there is a division ring $D(G)$ such that $\overline{\mathbb{Q}}[G] \subseteq D(G) \subseteq \mathcal{U}(G)$.*
