

# Comment on a Paper by Yucai Su On Jacobian Conjecture

T.T. Moh\*

January 22, 2018

## Abstract

The said paper [2] entitled "Proof Of Two Dimensional Jacobian Conjecture" is with gaps.

## Comments

J. Lipman sent us the URL of [2]. Harley Flanders of Michigan mentioned that: "*I would be very much interested in your opinions of Su's paper.*"

We have browsed Su's paper. There are at least 2 errors. (1): The author relied on the computations over a non-existing entity, *the associative algebra*  $\mathbf{F}[x,y][[y^{-1}]]$  (cf pg 5 of [2]). It is easy to see that if such a thing exists, we must have

$$1 + yy^{-1} + \cdots + y^i y^{-i} + \cdots = 1 + 1 + \cdots + 1 + \cdots$$

This is impossible. What the author really means is the ring  $K[x]((y^{-1}))$ , the ring of meromorphic functions over  $K[x]$ . The author should make the substitution throughout his paper.

(2): The author first use an (tame) automorphism  $x \mapsto x + y^k, y \mapsto y$  to satisfy the condition that  $f_0(x), g_0(x) \in F^*$  (on pg 7) (note that the degrees are increased), then use the same kind automorphism to reduce the degrees (on pg 15). This is a cyclic argument. The degrees may not be reduced.

## Suggestions to Yucai Su

We think that the author is making a noble attempt to solve a hard problem. The author should make the substitution mentioned in (1) above and consult article [1] (in there,  $\tau = F(x, y)^{-1/m}$  in Su's notation). To avoid a cyclic argument, one should use a general linear transformation instead of an (tame) automorphism  $x \mapsto x + y^k, y \mapsto y$  at the beginning. For the last thirty years, the only case one can not handle is the case of "more than one point at  $\infty$ ", i.e., in Su's notations,  $p = 1, j = m + n - 2$  (cf pg 17, Subcase), all other cases are well-known. The author should give an convincing argument for this case (in fact, for this case only).
