# ON THE EXISTENCE OF DISTORTION MAPS ON ORDINARY ELLIPTIC CURVES

DENIS CHARLES

### 1. INTRODUCTION

An important problem in cryptography is the so called Decision Diffie-Hellman problem (henceforth abbreviated DDH). The problem is to distinguish triples of the form  $(g^a, g^b, g^{ab})$  from arbitrary triples from a cyclic group  $G = \langle g \rangle$ . It turns out that for (cyclic subgroups of) the group of *m*-torsion points on an elliptic curve over a finite field, the DDH problem admits an efficient solution if there exists a suitable endomorphism called a distortion map (which can be efficiently computed) on the elliptic curve.

Suppose *m* is relatively prime to the characteristic of a finite field  $\mathbb{F}_q$ , then the group of *m*-torsion points on an elliptic curve  $E/\mathbb{F}_q$ , denoted E[m], is isomorphic to  $(\mathbb{Z}/m\mathbb{Z}) \times (\mathbb{Z}/m\mathbb{Z})$ . Fix an elliptic curve  $E/\mathbb{F}_q$  and a prime  $\ell$  that is not the characteristic of  $\mathbb{F}_q$ . Let *P* and *Q* generate the group  $E[\ell]$ . A distortion map on *E* is an endomorphism  $\phi$  of *E* such that  $\phi(P) \notin \langle P \rangle$ . A distortion map can be used to solve the DDH problem on the group  $\langle P \rangle$  as follows: Given a triple R, S, T of points belonging to the group generated by *P*, we check whether  $\mathbf{e}_{\ell}(R, \phi(S)) = \mathbf{e}_{\ell}(P, \phi(T))$ , where  $\mathbf{e}_{\ell}$  is the Weil pairing on the  $\ell$ -torsion points. It follows from well known properties of the Weil pairing that this check succeeds if and only if R = aP, S = bP and T = abP. Under the assumptions that *P* and *Q* are both defined over  $\mathbb{F}_{q^k}$ , where *k* is not large (say, bounded by a fixed polynomial in  $\log(q)$ ), and that  $\phi$  can be computed in polynomial time, the DDH problem can be solved in polynomial time using this idea. If *P* and *Q* are not eigenvectors for the Frobenius map, then in many cases one can use the trace map as a distortion map (see [GR04]). For this reason, we will concentrate only on the subgroups that are Frobenius eigenspaces.

It is known that distortion maps exist on supersingular elliptic curves ([Ver01, GR04]), and that distortion maps that do not commute with the Frobenius do not exist on ordinary elliptic curves (see [Ver01] or [Ver04] Theorem 6). The latter implies that distortion maps do not exist for ordinary elliptic curves with embedding degree > 1. The embedding degree, (say) k, is the order of q in the group  $(\mathbb{Z}/\ell\mathbb{Z})^*$ . A theorem of Balasubramanian and Koblitz ([BK98] Theorem 1) says that if  $E(\mathbb{F}_q)$  contains an  $\ell$ -torsion point and k > 1, then  $E[\ell] \subseteq \mathbb{F}_{q^k}$ . Thus, the only remaining cases where the existence of Distortion maps is not known are the cases when the embedding degree k is 1. If the embedding degree is 1 and  $E(\mathbb{F}_q)$  contains an  $\ell$ -torsion point, then there are two possibilities: either  $E[\ell](\mathbb{F}_q)$  is cyclic or  $E[\ell] \subseteq E(\mathbb{F}_q)$ . In the former situation there are no distortion maps (by [Ver04] Theorem 6). However, the Tate pairing can be used to solve DDH efficiently in this case (see the comments in [GR04] following Remark 2.2). Thus, the only case in which the question of the existence of a distortion map remains open is when  $E[\ell] \subseteq E(\mathbb{F}_q)$ . In this article we characterize the existence of distortion maps for this case.

### 2. The Proof

Let k be a finite field,  $\mathbb{F}_q \supseteq k$  and E/k be an ordinary elliptic curve. Suppose  $\ell$  is a prime such that  $E[\ell] \subseteq \mathbb{F}_q$  but no point of exact order  $\ell$  is defined over a smaller field.

To study the existence of distortion maps, we study the reduction of the ring  $\operatorname{End}(E) \mod \ell$ . Our principal tool is the following observation: If  $\alpha \in \operatorname{End}(E)$  has field polynomial  $f(x) \in \mathbb{Z}[x]$ , then  $f \mod \ell$  is the characteristic equation of the action of  $\alpha$  on  $E[\ell]$ .

Let  $\pi$  be the q-th power Frobenius endomorphism on E and let  $\phi^2 - t\phi + q = 0$  be its characteristic equation. We know that  $t \equiv 2 \mod \ell$  and  $q \equiv 1 \mod \ell$  as the full  $\ell$ -torsion is defined over  $\mathbb{F}_q$ . Let  $\mathcal{O} = \operatorname{End}(E)$ ,  $K = \mathcal{O} \otimes \mathbb{Q}$  and  $\mathcal{O}_K$  the maximal order in K. We have the inclusions  $\mathbb{Z}[\pi] \subseteq \mathcal{O} \subseteq \mathcal{O}_K$ . Since  $t^2 - 4q = 0 \mod \ell$  we have that  $\ell$  divides the product  $[\mathcal{O} : \mathbb{Z}[\pi]][\mathcal{O}_K : \mathcal{O}]\operatorname{Disc}(K)$ . The existence of distortion maps splits into cases depending on whether  $\ell | [\mathcal{O}_K : \mathcal{O}]$  or  $\ell | \operatorname{Disc}(K)$ . Indeed, if  $\ell | [\mathcal{O}_K : \mathcal{O}]$  there are no distortion maps, since the reduction modulo  $\ell$  of every endomorphism is just multiplication by scalar.

In the following we assume that  $\ell \not\mid [\mathcal{O}_K : \mathcal{O}]$  so that the conductor of  $\mathcal{O}$  is prime to  $\ell$ . Under this assumption we have that the residue class rings

$$\mathcal{O}_K/(\ell) \cong \mathcal{O}/(\ell).$$

Suppose that  $\ell \not\mid \operatorname{Disc}(K)$  and that  $\ell$  is *inert* in  $\mathcal{O}_K$ , then  $\mathcal{O}/(\ell) \cong \mathbb{F}_{\ell^2}$ . Let  $\alpha \in \mathcal{O}$  be an endomorphism such that  $\alpha \mod(\ell)$  does not lie in  $\mathbb{F}_{\ell}$ . Then the action of  $\alpha$  on  $E[\ell]$  is irreducible since its characteristic equation is irreducible over  $\mathbb{F}_{\ell}$ . Now  $\alpha$  gives us a distortion map on  $E[\ell]$  since no subgroup of order  $\ell$  of  $E[\ell]$  is stabilized by  $\alpha$ .

Now if  $\ell \not\mid \operatorname{Disc}(K)$  and  $\ell$  is *split* in  $\mathcal{O}_K$ , then  $\mathcal{O}/(\ell) \cong \mathbb{F}_{\ell}[X]/(X-a)(X-b) \cong (\mathbb{Z}/\ell\mathbb{Z})^2$  (where  $a \neq b$ ). The action of any  $\alpha \in O_K$ , that corresponds to the image of X in  $\mathbb{F}_{\ell}[X]/(X-a)(X-b)$  under the isomorphism, is conjugate to  $\begin{pmatrix} \gamma & 0 \\ 0 & \delta \end{pmatrix}$ . Thus, distortion maps exist for all but two of the subgroups of  $E[\ell]$ .

Suppose that  $\ell|\operatorname{Disc}(K)$  so that  $\ell$  is ramified in  $\mathcal{O}_K$ , then  $\mathcal{O}/(\ell) \cong \mathbb{F}_\ell[X]/(X-a)^2$ . Consider the map  $\alpha \in \mathcal{O}$  that corresponds to the image of X in the ring  $\mathbb{F}_\ell[X]/(X-a)^2$ . The action of  $\alpha$  on  $E[\ell]$  is conjugate to  $\begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix}$ . Note that  $\beta \neq 0$ , for if  $\beta = 0$  then  $\mathcal{O}/(\ell) \cong \mathbb{Z}/\ell\mathbb{Z}$ , but we know that  $\mathcal{O}$  is rank 2 over  $\mathbb{Z}/\ell\mathbb{Z}$  since  $\ell$  is ramified in  $\mathcal{O}_K$  and does not divide the conductor of  $\mathcal{O}$ . Thus, distortion maps exist for all but one subgroup of  $E[\ell]$ .

In summary, we have:

**Theorem 2.1.** Let k be a finite field,  $\mathbb{F}_q \supseteq k$  and E/k be an ordinary elliptic curve whose endomorphism ring is  $\mathcal{O}$ , an order in an imaginary quadratic field  $\mathcal{O}$ . Suppose  $\ell$  is a prime such that  $E[\ell] \subseteq \mathbb{F}_q$  but no point of exact order  $\ell$  is defined over a smaller field.

- (1) If  $\ell \mid [\mathcal{O}_K : \mathcal{O}]$  there are no distortion maps.
- (2) If ℓ / [O<sub>K</sub> : O]Disc(K) and
  (a) ℓ is inert in O<sub>K</sub>, then there are distortion maps for every (order ℓ) subgroup of E[ℓ];
  (b) ℓ is split in O<sub>K</sub>, then all but two subgroups of E[ℓ] have distortion maps.
- (3) If  $\ell \not\mid [\mathcal{O}_K : \mathcal{O}]$  and  $\ell \mid \text{Disc}(K)$  so that  $\ell$  is ramified in  $\mathcal{O}_K$ , then all (except one) subgroups of  $E[\ell]$  have distortion maps.

# 3. Examples

In this section, we give examples to illustrate that all the cases in Theorem 2.1 do occur.

**Example 3.1.** Consider the elliptic curve  $E : y^2 = x^3 + x$  over  $\mathbb{Q}$ . E has complex multiplication by  $\mathbb{Z}[i]$  and has good reduction at all odd primes. Let p be a prime such that  $p \equiv 1 \mod 4$ ,  $\tilde{E}$  be the reduction of E modulo p, and let  $i^2 = -1 \mod p$ . Then  $\tilde{E}[2] \subseteq \tilde{E}(\mathbb{F}_p)$  and  $\tilde{E}[2]$  is  $\{0_{\tilde{E}}, (0,0), (i,0), (-i,0)\}$  where  $0_{\tilde{E}}$  is the identity element. The map [i] is an endomorphism that sends  $(x, y) \mapsto (-x, iy)$ . It is easy to see that the map [i] preserves the subgroup  $\langle (0,0) \rangle$  and interchanges the remaining two subgroups, of order 2, of  $\tilde{E}[2]$ . Note, that Deuring's reduction theorem tells us that  $\operatorname{End}(\tilde{E}) \cong \mathbb{Z}[i]$ . Furthermore, in this case the subring  $\mathbb{Z}[\pi]$  generated by the Frobenius is usually a smaller ring. Indeed, if t is the trace of Frobenius and  $t^2 - 4p = -4b^2$ , then the conductor of the order  $\mathbb{Z}[\pi]$  is b. Now b is at least 2, since  $t \equiv 2 \mod 4$ , so (t/2) is odd and we must have  $p = (t/2)^2 + b^2$ . Thus, case (3) of Theorem 2.1 applies and matches with what we observe for the 2-torsion.

**Example 3.2.** (Suggested by anonymous reviewer). Let *E* be the curve over  $\mathbb{F}_{701}$  given by the equation  $y^2 = x^3 - 35x + 98$ . Then  $\operatorname{End}(E) = \mathbb{Z}[\frac{1+\sqrt{-7}}{2}]$  which is the maximal order in  $\mathbb{Q}(\sqrt{-7})$ . The order  $\mathbb{Z}[\pi]$ 

has conductor 10 in End(*E*). The 5-torsion is  $\mathbb{F}_{701}$  rational, and moreover, 5 is inert in End(*E*). Theorem 2.1 (2a) shows that every subgroup of *E*[5] admits a distortion map. Indeed, the map corresponding to multiplication by  $\alpha = \frac{1+\sqrt{-7}}{2}$  is given by ([Sil94] Chapter II, Proposition 2.3.1 (iii))

$$[\alpha](x,y) = \left(\alpha^{-2}\left(x - \frac{7(1-\alpha)^4}{x+\alpha^2 - 2}\right), \alpha^{-3}y\left(1 + \frac{7(1-\alpha)^4}{(x+\alpha^2 - 2)^2}\right)\right).$$

Let us check this for the group generated by the 5-torsion point P (with affine coordinates) P = (224, 31). Since  $\alpha = 386 \in \mathbb{F}_{701}$ , this tells us that  $[\alpha](P) = (173, 194)$ . One checks that the Weil pairing  $\mathbf{e}_5(P, [\alpha](P)) = 464 \neq 1$ . Thus,  $[\alpha]$  works as a distortion map for the group generated by P.

Now the 5-torsion of E is generated by P and the point Q = (573, 450). A similar computation shows that  $[\alpha](Q) = (463, 495)$ . Also,  $\mathbf{e}_5(Q, [\alpha]Q) = 89 \neq 1$ . Again, this shows that  $[\alpha]$  works as a distortion map.

Given these calculations it is not hard to find the matrix of the action of  $[\alpha]$  on E[5] relative to the basis P, Q

$$[\alpha] = \begin{pmatrix} 0 & -1 \\ 2 & 1 \end{pmatrix}.$$

The characteristic polynomial of this matrix is irreducible modulo 5 and thus the action on E[5] is irreducible.

**Example 3.3.** One can use the elliptic curve E from Example 3.2 to illustrate case (2b) of Theorem 2.1. This time we look at E[2] (also contained in  $\mathbb{F}_{701}$ ) which is generated by the points P = (319, 0) and Q = (389, 0). The prime 2 splits completely in End(E). The proof of Theorem 2.1 tells us that the characteristic polynomial of the action of the endomorphism [ $\alpha$ ] has two distinct roots and would work as a distortion map for all but two subgroups of E[2]. Now the minimal polynomial  $\alpha$  is  $x^2 - x + 2$  and modulo 2 this splits as x(x + 1). Thus the action of  $[\alpha]$  on E[2] will have two eigenvectors, with eigenvalues 0 and 1 respectively. It is easy to check given the formula for  $[\alpha]$  that indeed  $[\alpha](P) = 0_E$  and  $[\alpha](Q) = Q$ .

**Example 3.4.** In this example we illustrate that case (1) of Theorem 2.1 also occurs. Consider the curve  $E/\mathbb{Q}$  given by the Weierstrass equation

$$y^2 = x^3 - \frac{3375}{121}x + \frac{6750}{121}.$$

The *j*-invariant of E is  $2^4 3^3 5^3$  and the conductor of *E* is 108900. *E* has CM by the order of conductor 2 in  $\mathbb{Q}(\sqrt{-3})$ . Thus  $\operatorname{End}(E) \cong \mathbb{Z} + 2\mathcal{O}_K$  where  $\mathcal{O}_K = \mathbb{Z} + \frac{1}{2}(1 + \sqrt{-3})\mathbb{Z}$ . *E* has good reduction at the prime 13 and one sees that the reduction  $\tilde{E}$  has  $\mathbb{F}_{13}$ -rational 2-torsion. Now  $\operatorname{End}(\tilde{E}) \cong \operatorname{End}(E)$  by the Deuring reduction theorem ([Lan87] Chapter 13 §4, Theorem 12), but  $\operatorname{End}(\tilde{E}) \mod 2 \cong (\mathbb{Z}/2\mathbb{Z})$  and so there are no distortion maps.
