An infinitude of proofs of the infinitude of primes

L. J. P. Kilford

September 5, 2021

Dedicated to Yang-Hui He, for his 30th birthday.

Since Euclid's proof that there are infinitely many primes, there have been many different proofs of this theorem; some using topology, others combinatorics or number theory. In this note, we present a generalization of a method of Perott ([2], given in [3], which references [1], page 413) which gives infinitely many proofs of this theorem.

Let $m \geq 2$ be an integer. It is well-known that the sum $\sum_{n=1}^{\infty} (1/n^m)$ converges; moreover, it converges to a real number which is between 1 and 2, and is strictly less than 2, because $\sum_{n=1}^{\infty} (1/n^2) = \frac{\pi^2}{6} < 2$. We suppose that there are finitely many primes $p_1 < p_2 < \cdots < p_r$, and

We suppose that there are finitely many primes $p_1 < p_2 < \cdots < p_r$, and let N be a positive integer which is larger than the product of all of these primes. We will now divide the natural numbers $t \leq N$ into two classes; those which are m^{th} power free, and those which are divisible by an m^{th} power. There are m^r m^{th} power free numbers less than or equal to N, because this is the number of products of primes which are m^{th} power free. On the other hand, the number of integers $t \leq N$ which are divisible by p_i^m is at most N/p_i^m , so the number of natural numbers $t \leq N$ divisible by an m^{th} power is at most $\sum_{i=1}^r (N/p_i^m)$. Hence we have

$$N \le m^r + \sum_{i=1}^r \frac{N}{p_i^m} < m^r + N\left(\sum_{n=1}^\infty \frac{1}{n^m} - 1\right) = m^r + N(1 - \delta),$$

where $\delta > 0$. We now choose N such that $N\delta \ge m^r$, which we can do because m and r are fixed, and we obtain a contradiction. The infinitude of proofs follows because every natural number $m \ge 2$ suffices here; Perrot's proof used m = 2.
