Abstract.

It is pointed out that the usual derivation of the well-known Maxwell electromagnetic equations holds only for a medium at rest. A wayi n which the equations may be modified for the case when the mean flow of the medium is steady and uniform is proposed. The implication of this for the problem of theorigin of planetary magnetic fields is discussed.

Introduction.

Maxwell's electromagnetic equations are surely among the best known and most widely used sets of equations in physics. However, possibly because of this and since they have been used so successfully in so ma ny areas for somany years, they are, to some extent, taken for granted and used with little or no critical examination of their range of validit y. This is particularly true of the two equations

and

$$\nabla \times \mathbf{H} = 4\pi \mathbf{j} + \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t}$$

 $\nabla \times \mathbf{E} = -\frac{1}{c} \frac{\partial \mathbf{B}}{\partial t}$

Both these equations are used widely but, although the point is made quite clearly in most elementary, as well as more advanced, textbooks, i tis often forgotten that these equations apply *only* when the medium involved is assumed to be at rest. This assumption is actually crucial in the derivation of these equations since it is because of it that it is allowable to take the operator d/d t inside the integral sign as a partial derivative and so finally derive each of the above equations. This leaves open the question of what happensifthemedium is not at rest.

As is well known, for a non-conducting medium at rest, Maxwell's electromagneticequations, when no charge is present, reduce to

$$\nabla \cdot \mathbf{E} = 0, \quad \nabla \times \mathbf{E} = -\frac{\mu}{c} \frac{\partial \mathbf{H}}{\partial t},$$
$$\nabla \cdot \mathbf{H} = 0, \quad \nabla \times \mathbf{H} = \frac{\varepsilon}{c} \frac{\partial \mathbf{E}}{\partial t},$$

where $\mathbf{D} = \boldsymbol{\varepsilon} \mathbf{E}, \mathbf{B} = \boldsymbol{\mu} \mathbf{H}$ and $\boldsymbol{\mu}, \boldsymbol{\varepsilon}$ are assumed constantintime.

Thefirsttwoequationsareeasilyseentoleadto

$$\nabla^2 \mathbf{E} = \frac{\varepsilon \mu}{c^2} \frac{\partial^2 \mathbf{E}}{\partial t^2},$$

andthelattertwoto

$$\nabla^2 \mathbf{H} = \frac{\varepsilon \mu}{c^2} \frac{\partial^2 \mathbf{H}}{\partial t^2}.$$

Η

,

Therefore, in this special case, *provided* the medium is a trest, both E and satisfy the well-known wave equation. However, it has been shown [Thornhill, 1993] that, if the mean flow is steady and uniform, and, therefore both homentropic and irrotational, the system of equations governing small-amplitude homentropic irrotational wave motion in such a flow reduces to the equation

$$\nabla^2 \phi = (1/c^2) \mathbf{D}^2 \phi / \mathbf{D} t^2,$$

which is sometimes referred to as the convected, or progressive, wa ve equation.Thequestionwhichremainsis,forthecaseofamediumnotatrest, shouldMaxwell's electromagnetic equations be modified so as to reduc this progressive wave equation in the case of a non-conducting medium wit nocharge present?

GeneralisationofMaxwell'sequations.

Inthederivationof

$$\nabla \times \mathbf{E} = -\frac{\mu}{c} \frac{\partial \mathbf{H}}{\partial t}$$

itprovesnecessarytoconsidertheintegral

$$-\frac{\mu}{c}\frac{d}{dt}\int \mathbf{B}.\mathbf{dS}$$

and, as stated previously, interchange the derivative and the integral. This operation may be carried out only for a medium at rest. However, if the mediumismoving, then the surface Sinthein tegral will be moving also, and

the mere change of S in the field \mathbf{B} will cause changes in the flux. Hence, following Abraham and Becker [1932], a new kind of differentiation with respect to time is defined by the symbol $\dot{\mathbf{B}}$ as follows:

$$\frac{d}{dt}\int \mathbf{B}.\mathbf{dS} = \int \dot{\mathbf{B}}.\mathbf{dS} \qquad (a)$$

Here, $\hat{\mathbf{B}}$ is a vector, the flux of which across the moving surface equals the rate of increase with time of the flux of \mathbf{B} across the same surface. In order to find $\hat{\mathbf{B}}$, the exact details of the motion of the surface concerned must be known. Suppose this motion described by a vector \mathbf{u} , which is assumed given for each element dS of the surface and is the velocity of the element.

Let S_1 bethe position of the surface Sattime (t - dt) and S_2 the position at some later time t. S_2 may be obtained from S_1 by giving each element of S_1 a displacement $\mathbf{u}dt$. The surfaces S_1 and S_2 , together with the strip produced during the motion, bound avolume $dt \int \mathbf{u} \cdot \mathbf{dS}$.

The rate of change with time of the flux of the difference between the flux across S_2 at time tand that across S_1 at time (t-dt); that is

$$\frac{d}{dt}\int \mathbf{B}.\mathbf{dS} = \frac{\int \mathbf{B}_{t}.\mathbf{dS}_{2} - \int \mathbf{B}_{t-dt}.\mathbf{dS}_{1}}{dt}$$

where the subscriptindicates the time at which the flux is measured.

The divergence theorem may be applied at timet to the volume boundedby S_1 , S_2 and the strip connecting them. Here the required normal to S_2 willbe the outward pointing normal and that to S_1 the inward pointing normal.Also, a surface element of the side face will be given the orem givesven by $\mathbf{ds} \times \mathbf{u} dt$. Then, the

$$\int_{S_2} \mathbf{B}_t \cdot \mathbf{dS}_2 + dt \oint \mathbf{B} \cdot \mathbf{dS} \times \mathbf{u} - \int_{S_1} \mathbf{B}_t \cdot \mathbf{dS}_1 = dt \int (\nabla \cdot \mathbf{B}) \mathbf{u} \cdot \mathbf{dS} \cdot \mathbf{dS}_2$$

Also

$$\int \mathbf{B}_{t-dt} \cdot \mathbf{dS}_1 = \int \mathbf{B}_t \cdot \mathbf{dS}_1 - \int \frac{\partial \mathbf{B}}{\partial t} \mathbf{dS}_1 dt \; .$$

Hence,

$$\int \mathbf{B}_{t} \, \mathbf{dS}_{2} - \int \mathbf{B}_{t-dt} \, \mathbf{dS}_{1} = dt \Big\{ \int \dot{\mathbf{B}} \, \mathbf{dS}_{1} + \int (\nabla \cdot \mathbf{B}) \mathbf{u} \, \mathbf{dS}_{1} - \oint \mathbf{B} \, \mathbf{ds} \times \mathbf{u} \Big\}.$$

UsingStokes'theorem,thefinaltermontheright- handsideofthisequation maybewritten

$$\oint \mathbf{B}.\mathbf{ds} \times \mathbf{u} = \oint \mathbf{u} \times \mathbf{B}.\mathbf{ds} = \int \{\nabla \times (\mathbf{u} \times \mathbf{B})\}.\mathbf{dS},$$

sothatfinally

$$\frac{d}{dt}\int \mathbf{B}.\mathbf{dS} = \int \left\{ \frac{\partial \mathbf{B}}{\partial t} + \mathbf{u}(\nabla,\mathbf{B}) - \nabla \times (\mathbf{u} \times \mathbf{B}) \right\}.\mathbf{dS}.$$

Therefore, the $\dot{\mathbf{B}}$, introduced in equation (a) above, is given by

$$\dot{\mathbf{B}} = \frac{\partial \mathbf{B}}{\partial t} + \mathbf{u}(\nabla \cdot \mathbf{B}) - \nabla \times (\mathbf{u} \times \mathbf{B})$$

or,notingthat

$$\nabla \times (\mathbf{u} \times \mathbf{B}) = \mathbf{u}(\nabla . \mathbf{B}) - \mathbf{B}(\nabla . \mathbf{u}) + (\mathbf{B} . \nabla)\mathbf{u} - (\mathbf{u} . \nabla)\mathbf{B},$$
$$\dot{\mathbf{B}} = \frac{\partial \mathbf{B}}{\partial t} + (\mathbf{u} . \nabla)\mathbf{B} + \mathbf{B}(\nabla . \mathbf{u}) - (\mathbf{B} . \nabla)\mathbf{u}$$

However, if the mean flow is steady and uniform and here and here and here and here and irrotational, the fluid velocity,**u**, will be constant and this latter equation will reduce to

$$\dot{\mathbf{B}} = \frac{\partial \mathbf{B}}{\partial t} + (\mathbf{u} \cdot \nabla) \mathbf{B} = \frac{D\mathbf{B}}{Dt},$$

that is, for such flow, \mathbf{B} becomes the well-known Euler derivative. It might be noted, though, that, for more general flows, the expression for \mathbf{B} is somewhatmore complicated.

It follows that, if the mean flow is steady and uni form, the Maxwell equation, mentioned above, becomes

$$\nabla \times \mathbf{E} = -\frac{\mu}{c} \frac{D\mathbf{H}}{Dt} = -\frac{\mu}{c} \left[\frac{\partial \mathbf{H}}{\partial t} + (\mathbf{u} \cdot \nabla) \mathbf{H} \right].$$

Also, in this particular case, there maining three Maxwell equations will be

$$\nabla \mathbf{E} = 0, \quad \nabla \mathbf{H} = 0,$$

$$\nabla \times \mathbf{H} = \frac{\varepsilon}{c} \frac{D\mathbf{E}}{Dt} = \frac{\varepsilon}{c} \left[\frac{\partial \mathbf{E}}{\partial t} + (\mathbf{u} \cdot \nabla) \mathbf{E} \right],$$

with this form for the final equation following in a manner similar to that adopted above when noting that, for a steady, unifor replaced by D/D *t* in the equation for $\nabla \times \mathbf{E}$.

These four modified Maxwell equations lead to both **E** and **H** satisfying heysurely must.

Theoriginofplanetarymagneticfields.

It is conceivable that use of these modified Maxwell electromagnetic equations could provide new insight into the proble m of the origin of planetary magnetic fields. This is a problem which has existed, without a really satisfactory explanation, for many years. I twouldseemreasonableto expect all such fields to arise from the same physi cal mechanism, although the minute detail might vary from case to case. The mechanism generally favoured as providing the best explanation for the originofthesefieldswas the dynamo mechanism, although the main reason for its adoption was the failure of the alternatives to provide a consistent explanation. However, Cowling [1934] showed that there is a limit to the degree of symmetry encountered in a steady dynamo mechanism; this resu lt, based on the

traditional electromagnetic equations of Maxwell, s hows that the steady maintenanceofapoloidalfieldissimplynotpossi ble-theresultisinreality an anti-dynamo theorem which raises difficulties in understanding the observedsymmetryofthedipolefield.

Following Alfvén [1963], it might be noted th at, in a stationary state, there is no electromagnetic field along a neutral l ine because that would imply a non-vanishing $\nabla \times \mathbf{E}$, and so a time varying **B**. The induced electric field $\mathbf{v} \times \mathbf{B}$ vanishes on the neutral line since **B** does. Thus, there can be no electromotiveforcealongtheneutralline, and the reforethecurrentdensityin the stationary state vanishes, the conductivity bei ng infinite. On the other hand, $\nabla \times \mathbf{B}$ does not vanish on the neutral line. By Maxwell's usual equations, the non-vanishing $\nabla \times \mathbf{B}$ and the vanishing current density are in contradiction and so the existence of a rotationall y symmetric steady-state dynamo is disproved. However, this conclusion may n ot be drawn if the modified Maxwell equations, alluded to earlier, are used, since, even in the steadystatewherethepartialderivativeswithres pecttotimewillallbezero, the equation for $\nabla \times \mathbf{B}$ will reduce to

$$\nabla \times \mathbf{B} = \frac{1}{\mu} \left[\mathbf{j} + \varepsilon \frac{\partial \mathbf{E}}{\partial t} + \varepsilon \mathbf{v} \cdot \nabla \mathbf{E} \right] \rightarrow \frac{\varepsilon}{\mu} \mathbf{v} \cdot \nabla \mathbf{E}$$

and there is no reason why this extra term on theright-hand side should beidentically equal to zero. Also, the non-vanishingof $\nabla \times \mathbf{E}$ will not imply atime varying \mathbf{B} since, once again, there is an extra term- $\mathbf{v} \cdot \nabla \mathbf{B}$ remaining toequate with the $\nabla \times \mathbf{E}$. It follows that an electromagnetic field may existalongthe neutral line under these circumstances. Hence,no contradiction occurs;instead, aconsistent system of differential equation sremain stobes olved.
