# Filtering and Control in Quantum Optics

Luc Bouten

# Filtering and Control in Quantum Optics

een wetenschappelijke proeve op het gebied van de Natuurwetenschappen, Wiskunde en Informatica

Proefschrift

ter verkrijging van de graad van doctor aan de Radboud Universiteit Nijmegen op gezag van de Rector Magnificus prof. dr. C.W.P.M. Blom, volgens het besluit van het College van Decanen in het openbaar te verdedigen op maandag 29 november 2004 des morgens om 10.30 precies door

Lucas Martinus Bouten

geboren op 11 oktober 1976 te Helden

Promotor: Prof. Dr. G.J. Heckman

Copromotor: Dr. J.D.M. Maassen

# Manuscriptcommissie:

Prof. Dr. V.P. Belavkin (University of Nottingham) Prof. Dr. R.D. Gill (University of Utrecht) Prof. Dr. B. Kümmerer (University of Darmstadt)

ISBN 90-9018790-1

# Acknowledgments

The theme for this thesis, applying the tools of quantum probability to problems in quantum optics, was provided by Hans Maassen, who has been my supervisor for the past four years. Apart from sharing his deep insight in quantum mechanics, I am grateful to Hans for his patience and encouragement in finding my own way in research. I would like to extend these words of thanks to Mădălin Guță, my colleague in Nijmegen in the first two years, and a good friend in close scientific contact afterwards. I have benefited a lot from the seminar on operator algebras organised by our little group in Nijmegen for the first two years. It grew to become the "QRandom seminar" in collaboration with Richard Gill's groups in Eindhoven and Utrecht afterwards.

The last four years I have been in very pleasant and friendly contact with Gert Heckman, who has advised and encouraged me on numerous occasions. I am grateful to Gert for the many enriching discussions on mathematics we have had over the years. Gert has also encouraged me to attend the seminar on noncommutative geometry organised by Klaas Landsman and Eric Opdam in Amsterdam, which was a very stimulating experience.

In the second year Hans sent me to Oregon (USA) on a three month visit to Howard Carmichael. This visit proved to be a turning point for me. Howard introduced me to the stochastic Schrödinger equations and he also provided me with literature pointing me in the direction of quantum filtering theory. Apart from showing me a new direction in research, I am grateful to him for the many things he taught me about quantum optics and for his kind hospitality.

In the last year I met Slava Belavkin who invited me to Nottingham. I am thankful to him for the many discussions we had on quantum filtering theory. I am also grateful to him for introducing me to optimal control theory in a quantum setting, a line of research in which I would like to continue in the future. I thank Slava and Martin Lindsay for arranging the nice time spent in Nottingham.

I am indebted to Andreas Buchleitner for organising the many workshops I attended at the Max Planck Institut in Dresden. I also thank him for his advice in rewriting the introduction to the paper that makes up Chapter 3 of this thesis. I am thankful to Burkhard Kümmerer for his inspiring lectures at the "Coherent Evolution in Noisy Environments" summer school in Dresden, and for his interest and encouragement in the work I have done.

I thank Joost and Stefan, with whom I shared an office, and many friends for the pleasant atmosphere of the past four years. I thank my parents for their support.

# Chapter 1

# Introduction

Sixty years after its invention by the Japanese mathematician Kiyosi Itô, stochastic analysis has found a wide range of applications varying from pure mathematics to physics, enginering, biology and economics. Stochastic differential equations are an important tool for solving problems in pricing options at the stock market, finding solutions to boundary value problems, filtering signals in electrical enginering and for solving many other problems. In 1984 Hudson and Parthasarathy published a paper [54] extending the definition of Itô's stochastic integral and its subsequent calculus to the non-commutative world of quantum mechanics. The goal of this thesis is to apply this generalized stochastic calculus to problems in quantum optics.

# 1.1 Some spectral theory and quantum probability

The question of the mathematical foundations of quantum mechanics was settled by von Neumann in a series of papers written between 1927 and 1932, culminating in his book "Mathematische Grundlagen der Quantenmechanik" [87]. In this series of articles von Neumann developed spectral theory for normal operators on a Hilbert space, i.e. operators that commute with their adjoint. Avoiding tedious considerations regarding domains of operators we will now first focus on spectral theory for bounded normal operators on a separable Hilbert space  $\mathbb{H}$ .

Denote by  $\mathcal{B}(\mathbb{H})$  the algebra of all bounded operators on  $\mathbb{H}$  and let  $\mathcal{S}$  be a subset of  $\mathcal{B}(\mathbb{H})$ . We call the set  $\mathcal{S}' := \{R \in \mathcal{B}(\mathbb{H}); SR = RS \ \forall S \in \mathcal{S}\}$  the *commutant* of  $\mathcal{S}$  in  $\mathcal{B}(\mathbb{H})$ . A *von Neumann algebra*  $\mathcal{A}$  on  $\mathbb{H}$  is a \*-subalgebra of  $\mathcal{B}(\mathbb{H})$  such that  $\mathcal{A}$  equals its double commutant, i.e.  $\mathcal{A}'' = \mathcal{A}$ . It follows from von Neumann's double commutant theorem, cf. [55], that a von Neumann algebra is a  $C^*$ -subalgebra, i.e. a \*-subalgebra closed in the operator norm topology, of  $\mathcal{B}(\mathbb{H})$  that is closed even in the weak operator topology.

It immediately follows from  $\mathcal{A}'' = \mathcal{A}$  that the identity  $\mathbf{1} \in \mathcal{B}(\mathbb{H})$  is an element of the von Neumann algebra  $\mathcal{A}$ . A state on  $\mathcal{A}$  is a linear map  $\rho : \mathcal{A} \to \mathbb{C}$  such that  $\rho$  is positive in the sense that  $\rho(\mathcal{A}^*\mathcal{A}) \geq 0$  for all  $\mathcal{A} \in \mathcal{A}$  and such that  $\rho$  is normalised  $\rho(\mathbf{1}) = 1$ . A state is called normal if it is weak operator continuous on the unit ball of  $\mathcal{A}$ . The following theorem, see [56] sections 9.3, 9.4 and 9.5 for a proof, is at the heart of spectral theory.

**Theorem 1.1.1:** Let  $\mathcal{C}$  be a commutative von Neumann algebra and  $\rho$  a normal state on  $\mathcal{C}$ . Then there is a probability space  $(\Omega, \Sigma, \mathbb{P})$  such that  $\mathcal{C}$  is \*-isomorphic to  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$ , the space of all bounded measurable functions on  $\Omega$ . Furthermore, if we denote the \*-isomorphism between  $\mathcal{C}$  and  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$  by  $C \mapsto C_{\bullet}$  we have

$$\rho(C) = \int_{\Omega} C_{\omega} \mathbb{P}(d\omega), \quad C \in \mathcal{C},$$

where  $C_{\omega}$  denotes the function  $C_{\bullet}$  evaluated at  $\omega$ , i.e.  $C_{\omega} = C_{\bullet}(\omega)$ .

Since a normal operator, i.e. an operator that commutes with its adjoint, generates a commutative von Neumann algebra the above theorem can be applied. The simplest example of a normal operator is a Hermitian operator A on a finite dimensional Hilbert space. The above theorem then states that A is equivalent with a function  $A_{\bullet}$  and that the algebra generated by A is isomorphic to the algebra generated by this function  $A_{\bullet}$ . Indeed, after diagonalisation, A is equivalent with the function that maps i, standing for diagonal entry number i, to its corresponding eigenvalue. Note that the above theorem also covers simultaneous diagonalisation of several commuting Hermitian operators.

Given a probability space  $(\Omega, \Sigma, \mathbb{P})$ , we can study the commutative von Neumann algebra  $\mathcal{B} := L^{\infty}(\Omega, \Sigma, \mathbb{P})$ , acting on the Hilbert space  $L^2(\Omega, \Sigma, \mathbb{P})$  by pointwise multiplication, equipped with the normal state  $\rho$  given by expectation with respect to the measure  $\mathbb{P}$ . The pair  $(\mathcal{B}, \rho)$  faithfully encodes the probability space  $(\Omega, \Sigma, \mathbb{P})$  [70]. Indeed, the  $\sigma$ -algebra  $\Sigma$  can be reconstructed (up to equivalence of sets with symmetric difference 0, a point on which we will not dwell here) as the set of projections in  $\mathcal{B}$ , i.e. the set of characteristic functions of sets in  $\Sigma$ , and the probability measure is given by acting with the state  $\rho$  on this set of projections. We conclude that studying commutative von Neumann algebras equipped with normal states is the same as studying probability spaces. This motivates the definition of a *non-commutative* or *quantum* probability space as a von Neumann algebra equipped with a normal state.

From the point of view of physics it is violation of Bell's inequalities [21] in for instance the Aspect experiment [6], that motivates the study of non-commutative probability. See for instance [64] for a clear exposition of the point that this violation can not be accounted for

by a local classical probabilistic model. The way out if one wants to preserve locality is to weaken Kolmogorov's axioms of probability ending up with a non-commutative probability theory, namely quantum mechanics.

Let  $(\mathcal{B}, \rho)$  be a quantum probability space. The events are given by the projections in  $\mathcal{B}$ , i.e. elements satisfying  $E^2 = E = E^*$ . Two events E and F are called *compatible* if EFis again an event, which is equivalent to EF = FE. The interpretation is such that only events that are compatible can occur simultaneously. Note that in classical probability, i.e.  $\mathcal{B}$  is commutative, all events are compatible. If E and F are compatible events then EF stands for the occurence of both E and F and  $E \lor F := E + F - EF$  stands for the occurence of E or F or both. When an event E has occurred we have to update the state  $\rho$  to  $\rho_E$  with  $\rho_E(A) = \rho(EAE)/\rho(E)$ , the state conditioned on E.

In classical probability theory a random variable X is a measurable map from a probability space  $(\Omega, \Sigma, \mathbb{P})$  to some other measure space  $(\Omega', \Sigma')$ . The probability distribution of X is given by

$$\mathbb{P}_X: \ \Sigma' \to [0,1]: S \mapsto \mathbb{P}(X^{-1}(S)).$$

Algebraically X is completely determined by the pull back

$$j_X: L^{\infty}(\Omega', \Sigma', \mathbb{P}_X) \to L^{\infty}(\Omega, \Sigma, \mathbb{P}): f \mapsto f \circ X.$$

This motivates the definition of a random variable on a quantum probability space  $(\mathcal{B}, \rho)$ as a \*-homomorphism j from some other von Neumann algebra  $\mathcal{A}$  to  $\mathcal{B}$  mapping  $\mathbf{1}_{\mathcal{A}}$  to  $\mathbf{1}_{\mathcal{B}}$ . The probability distribution of j is then given by  $\sigma := \rho \circ j$  on  $\mathcal{A}$ . A quantum stochastic process [1] is a family  $\{j_t\}_{t\in\mathbb{T}}$  of random variables indexed by time  $\mathbb{T}$  which is a linearly ordered set such as  $\mathbb{N}, \mathbb{Z}, \mathbb{R}$  or  $\mathbb{R}_+$ . See [61] for theory on non-commutative Markov processes.

Let  $j : \mathcal{A} \to \mathcal{B}$  be a random variable on  $(\mathcal{B}, \rho)$ . If  $\mathcal{A} = L^{\infty}(\mathbb{R})$  then j is called a *real* valued random variable. The following brief exposition of spectral theory for unbounded selfadjoint operators shows that there is a one-to-one correspondence between real valued random variables and selfadjoint operators. Given j we can define a projection valued measure on the Borel sigma-algebra  $\Sigma$  of  $\mathbb{R}$  by

$$E(S) := j(\chi_S), \quad S \in \Sigma,$$

where  $\chi_S$  stands for the characteristic function of S, i.e. the function that is 1 on S and 0 elsewhere. We can now define a selfadjoint operator A by

$$A = \int_{\mathbb{R}} \lambda E(d\lambda). \tag{1.1}$$

Conversely, since the spectrum of a selfadjoint operator A is real, we can define bounded operators  $T_+ := (A + i\mathbf{1})^{-1}$  and  $T_- := (A - i\mathbf{1})^{-1}$ . The operators  $T_+$  and  $T_-$  generate a commutative von Neumann algebra  $\mathcal{A}$ . From Theorem 1.1.1 it follows that there exist a measurable space  $(\Omega, \Sigma')$  and a \*-isomorphism  $i : L^{\infty}(\Omega, \Sigma') \to \mathcal{A}$ . Define a measurable function  $A_{\bullet}$  from  $\Omega$  to the extended reals  $\overline{\mathbb{R}}$  by

$$A_{\bullet} := \frac{\left(i^{-1}(T_{+})\right)^{-1} + \left(i^{-1}(T_{-})\right)^{-1}}{2}.$$
(1.2)

Then we can define a projection valued measure on the Borel sigma algebra of  $\mathbb{R}$ , generated by the sets  $(-\infty, \lambda]$  with  $\lambda \in \mathbb{R}$ , by

$$E((-\infty,\lambda]) := i(\chi_{[A_{\bullet} \leq \lambda]}),$$

and in this way equation (1.1) reappears. Furthermore the spectral measure, in its turn, uniquely determines a real valued random variable  $j : L^{\infty}(\mathbb{R}) \to \mathcal{B}$ . The above expositions shows three equivalent ways of characterising real valued random variables or *observables*, i.e. by a selfadjoint operator A, by a projection valued measure E, and by a \*-homomorphism j. A fourth way of looking at random variables is provided by Stone's theorem, see for instance [55].

**Theorem 1.1.2:** (Stone's theorem) There is a one-to-one correspondence between strongly continuous unitary representations  $t \mapsto U_t$  of the abelian group  $\mathbb{R}$  into a von Neumann algebra  $\mathcal{A}$  and selfadjoint operators A affiliated to  $\mathcal{A}$ , i.e. having all its spectral projections in  $\mathcal{A}$ , such that

$$U_t = \exp(itA) := \int_{\mathbb{R}} e^{it\lambda} E(d\lambda).$$

Let  $\mathcal{A}$  and  $\mathcal{B}$  be von Neumann algebras. We denote their Banach space duals by  $\mathcal{A}^*$  and  $\mathcal{B}^*$ , respectively. A linear map  $T : \mathcal{A} \to \mathcal{B}$  determines a dual map  $T^* : \mathcal{B}^* \to \mathcal{A}^*$  by  $\rho \mapsto \rho \circ T$ . An element A of a  $C^*$ -algebra is called *positive* if it can be written as  $A = B^*B$  for some Bin that  $C^*$ -algebra. Recall that von Neumann algebras are a special class of  $C^*$ -algebras. The map  $T^*$  maps states on  $\mathcal{B}$  to states on  $\mathcal{A}$  if and only if T is *positive*, in the sense that it maps positive elements of  $\mathcal{A}$  into positive elements of  $\mathcal{B}$ , and  $T(\mathbf{1}_{\mathcal{A}}) = \mathbf{1}_{\mathcal{B}}$ . The map T is said to be *completely positive* if for all  $n \in \mathbb{N}$  the map  $T \otimes \mathrm{Id}_n : \mathcal{A} \otimes M_n(\mathbb{C}) \to \mathcal{B} \otimes M_n(\mathbb{C})$ is positive. An *operation* T is a completely positive map such that  $T(\mathbf{1}_{\mathcal{A}}) = \mathbf{1}_{\mathcal{B}}$  and its dual  $T^*$  is also called an *operation*. An operation  $T^* : \mathcal{B}^* \to \mathcal{A}^*$  represent some physical procedure which takes as an input a state on a quantum system described by  $\mathcal{B}$  and turns out a state on the quantum system  $\mathcal{A}$ . The *complete* positivity ensures that operations on a quantum system  $\mathcal{A}$  can always be extended to operations on  $\mathcal{A} \otimes \mathcal{W}$ , the quantum system  $\mathcal{A}$  with its environment  $\mathcal{W}$ .

The operational approach to quantum mechanics was pioneered by Davies and Lewis [34], [33], [37]. In this approach all physical procedures performed on quantum systems are given by operations between their algebras of observables. An example of an operation is a random variable, i.e. a \*-homomorphism *i* from an algebra  $\mathcal{A}$  to  $\mathcal{B}$ . Suppose  $\mathcal{B} = \mathcal{A} \otimes \mathcal{W}$  and  $i = \text{Id} \otimes \mathbf{1}_{\mathcal{W}}$ , then the dual of i is what is known in physics as a partial trace, i.e. restriction of the state to the smaller system  $\mathcal{A} \otimes \mathbf{1}_{\mathcal{W}}$ . A second example is adjoining with a unitary operator or a projection, i.e. time evolution or conditioning on a measurement result, respectively. A third example of an operation is a *conditional expectation*, the topic of the next paragraph.

Let  $\mathcal{B}$  be a von Neumann subalgebra of a von Neumann algebra  $\mathcal{A}$ . A conditional expectation of  $\mathcal{A}$  onto  $\mathcal{B}$  is a linear surjective map  $\mathcal{E} : \mathcal{A} \to \mathcal{B}$  such that  $\mathcal{E}^2 = \mathcal{E}$  and  $\|\mathcal{E}\| = 1$ . We are interested in a conditional expectation  $\mathcal{E}_{\rho} : \mathcal{A} \to \mathcal{B}$  that leaves a certain state  $\rho$  on  $\mathcal{A}$ invariant, i.e.  $\rho \circ \mathcal{E}_{\rho} = \rho$ . However, such a conditional expectation does not always exist, but if it exists it is unique [84]. The interpretation is as follows, if we start with a quantum system  $\mathcal{A}$  in a state  $\rho$  and we gain (for example by observation) the additional information that  $\mathcal{B}$  is in a state  $\sigma$ , then  $\sigma \circ \mathcal{E}_{\rho}$  is the updated state of  $\mathcal{A}$  [62]. It follows from [85] that  $\mathcal{E}_{\rho}$  is an operation and that it satisfies the module property:  $\mathcal{E}_{\rho}(B_1AB_2) = B_1\mathcal{E}_{\rho}(A)B_2$  for all  $B_1, B_2 \in \mathcal{B}$  and  $A \in \mathcal{A}$ . An example of a conditional expectation is given by taking  $\mathcal{A} = \mathcal{B} \otimes \mathcal{W}$  and  $\mathcal{E} = \mathrm{Id} \otimes \phi$  with  $\phi$  a state on  $\mathcal{W}$ . If  $\mathcal{A}$  is a commutative algebra then we retrieve the conditional expectation of classical probability theory.

## **1.2** Stochastic calculus on Fock spaces

Let  $\mathbb{H}$  be a Hilbert space and think of its elements as the pure states of one particle in quantum mechanics. The particles we are interested in are photons. Since photons are bosons they have to be described by symmetrised wave functions. This motivates the definition of the symmetric Fock space over  $\mathbb{H}$  as

$$\mathcal{F}(\mathbb{H}) := \mathbb{C} \oplus \bigoplus_{n=1}^{\infty} \mathbb{H}^{\otimes_s n}.$$

It describes situations where the number of particles present is arbitrary. For every  $f \in \mathbb{H}$  we define the *exponential vector*  $e(f) \in \mathcal{F}(\mathbb{H})$  by

$$e(f) := 1 \oplus \bigoplus_{n=1}^{\infty} \frac{1}{\sqrt{n!}} f^{\otimes n}.$$

The linear span  $\mathcal{D}$  of all exponential vectors is a dense subspace of  $\mathcal{F}(\mathbb{H})$ . On the dense domain  $\mathcal{D}$  we define for all  $f \in \mathbb{H}$  an operator W(f) by

$$W(f)e(g) := \exp\left(-\langle f, g \rangle - \frac{1}{2} \|f\|^2\right) e(f+g), \quad g \in \mathbb{H},$$
(1.3)

which is isometric and therefore uniquely extends to a unitary operator on  $\mathcal{F}(\mathbb{H})$ . The operators  $W(f) : \mathcal{F}(\mathbb{H}) \to \mathcal{F}(\mathbb{H})$  are called *Weyl operators* and they satisfy the following

Weyl relations

1. 
$$W(f)^* = W(-f), \quad f \in \mathbb{H},$$
  
2.  $W(f)W(g) = \exp\left(-i\mathrm{Im}\langle f, g\rangle\right)W(f+g), \quad f, g \in \mathbb{H}.$ 
(1.4)

For all  $f \in \mathbb{H}$  the family  $\{W(tf)\}_{t \in \mathbb{R}}$  forms a one-parameter group, continuous in the strong operator topology. Therefore it follows from Stone's theorem 1.1.2 that for all  $f \in \mathbb{H}$  there exists a selfadjoint B(f) such that

$$W(tf) = \exp\left(itB(f)\right).$$

The operators B(f) are called *field operators*, see also Section 1.3. The domain of the operator  $B(f_k) \dots B(f_1)$  contains  $\mathcal{D}$  for every  $f_1, \dots f_k \in \mathbb{H}$  and  $k \in \mathbb{N}$  (cf. [75]). For  $f, g \in \mathbb{H}$  and  $t \in \mathbb{R}$  it follows from the Weyl relations that on the domain  $\mathcal{D}$ 

1. 
$$B(tf) = tB(f),$$
  
2.  $B(f+g) = B(f) + B(g),$  (1.5)  
3.  $[B(f), B(g)] = 2i \text{Im} \langle f, g \rangle.$ 

Let us take  $\mathbb{H} = L^2(\mathbb{R})$  and let us consider it in the canonical way as a real space, then the pair  $(\mathbb{H}, \operatorname{Im}\langle \cdot, \cdot \rangle)$  forms a symplectic space. Denote by  $H_0$  the real subspace of  $\mathbb{H}$  given by  $\{f = (f_1, f_2) \in H; f_2 = 0\}$ . From (1.5.3) it immediately follows that the family of operators  $\{B(f); f \in H_0\}$  is commutative.

As in the previous section we can consider the bounded operators  $T(f)_+ := (B(f) + i\mathbf{1})^{-1}$ and  $T(f)_- := (B(f) - i\mathbf{1})^{-1}$  for  $f \in H_0$ . They generate a commutative von Neumann algebra  $\mathcal{C}$ . We denote by  $\phi$  the state on  $\mathcal{C}$  given by

$$\phi(C) := \langle \Phi, C\Phi \rangle$$
, with  $\Phi = 1 \oplus 0 \oplus 0 \dots \in \mathcal{F}(\mathbb{H})$ .

Using Theorem 1.1.1 we see that  $(\mathcal{C}, \phi)$  is isomorphic to  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$  for some probability space  $(\Omega, \Sigma, \mathbb{P})$ . We denote this isomorphism from  $\mathcal{C}$  to  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$  by  $C \mapsto C_{\bullet}$ . As in the previous section, see equation (1.2), we can let the operator B(f)  $(f \in H_0)$ , affiliated with  $\mathcal{C}$ , correspond to a measurable function  $B(f)_{\bullet}$  on  $\Omega$  taking values in the extended reals  $\mathbb{R}$ .

The joint characteristic function of the random variables  $B(f_1)_{\bullet}, B(f_2)_{\bullet}, \ldots, B(f_k)_{\bullet}$  is for

#### $x_1, \ldots, x_k \in \mathbb{R}$ given by

$$\mathbb{E}\left[e^{ix_{1}B(f_{1})\bullet}e^{ix_{2}B(f_{2})\bullet}\dots e^{ix_{k}B(f_{k})\bullet}\right] = \int_{\Omega} e^{ix_{1}B(f_{1})\omega}e^{ix_{2}B(f_{2})\omega}\dots e^{ix_{k}B(f_{k})\omega}\mathbb{P}(d\omega) = \left\langle\Phi, e^{ix_{1}B(f_{1})}e^{ix_{2}B(f_{2})}\dots e^{ix_{k}B(f_{k})}\Phi\right\rangle = \left\langle\Phi, \exp\left(i\sum_{i=1}^{k}x_{i}B(f_{i})\right)\Phi\right\rangle = \left\langle\Phi, W\left(\sum_{i=1}^{k}x_{i}f_{i}\right)\Phi\right\rangle = \exp\left(-\frac{1}{2}\sum_{i,j=1}^{k}x_{i}x_{j}\langle f_{i}, f_{j}\rangle\right),$$
(1.6)

where we used Theorem 1.1.1 in the second step and equation (1.5.1) and (1.5.2) in the fourth step. For  $t \in \mathbb{R}$  we define a random variable  $B_t := B(\chi_{[0,t)})_{\bullet}$  where  $\chi_{[0,t)}$  stands for the function that is 1 on the interval [0,t) and 0 elsewhere. For  $s_1 \leq t_1 \leq s_2 \leq t_2$  it immediately follows from (1.6) that the joint characteristic function of the increments  $B_{t_1} - B_{s_1} = B(\chi_{[s_1,t_1]})_{\bullet}$  and  $B_{t_2} - B_{s_2} = B(\chi_{[s_2,t_2]})_{\bullet}$  factorizes

$$\mathbb{E}\left[e^{ix(B_{t_1}-B_{s_1})}e^{iy(B_{t_2}-B_{s_2})}\right] = \exp\left(-\frac{1}{2}\left(x^2(t_1-s_1)+y^2(t_2-s_2)\right)\right) = \exp\left(-\frac{x^2(t_1-s_1)}{2}\right)\exp\left(-\frac{y^2(t_2-s_2)}{2}\right) = \mathbb{E}\left[e^{ix(B_{t_1}-B_{s_1})}\right]\mathbb{E}\left[e^{iy(B_{t_2}-B_{s_2})}\right]$$

i.e.  $\{B_t\}_{t\geq 0}$  is a process with independent increments. Furthermore, from its characteristic function it follows that the increments  $B_t - B_s$  are normally distributed with mean zero and variance t - s. Summarizing, the process  $\{B_t\}_{t\geq 0}$  is a *Brownian motion*.

The idea to simultaneously diagonalise the fields in the family  $\{B(\chi_{[0,t)}); t \geq 0\}$  is implicit is some of the earliest work in quantum field theory. However, Segal [78] in the 1950s was the first to emphasise the connection with probability theory. See also [80] for a nice review of the importance of these ideas for Euclidean quantum field theory.

Fix  $\alpha$  in the interval  $[0, \pi)$ . Then, as in the previous paragraph, the family of operators  $B(e^{i\alpha}\chi_{[0,t)})$  is commutative. This means there is a probability space  $(\Omega_{\alpha}, \Sigma_{\alpha}, \mathbb{P}_{\alpha})$  on which the operators  $B(e^{i\alpha}\chi_{[0,t)})$  are realised as random variables  $B(e^{i\alpha}\chi_{[0,t)})_{\bullet} =: B_t^{\alpha}$ . In a similar fashion as in the previous paragraph it can be shown that the process  $\{B_t^{\alpha}\}_{t\geq 0}$  is a Brownian motion. However, for two different alphas, i.e.  $\alpha_1$  and  $\alpha_2$ , it follows from equation (1.5.3) that the Brownian motions  $B_t^{\alpha_1}$  and  $B_t^{\alpha_2}$  do not commute. For instance we have

$$[B_s^0, B_t^{\pi/2}] = 2i\min\{s, t\}.$$

Expression (1.5.3) is known as the *canonical commutation relation*. It is clear that the Weyl relation (1.4.2) is an exponentiated form of the canonical commutation relation. Weyl operators have the advantage that they are bounded, so that there are no domain problems involved. That is why we abstractly define the  $C^*$ -algebra of canonical commutation

relations  $CCR(H, \sigma)$  with respect to some symplectic space  $(H, \sigma)$  as the  $C^*$ -algebra generated by abstract elements W(f)  $(f \in H)$  satisfying the relations in (1.4) where  $\mathbb{H}$ and  $\operatorname{Im}\langle \cdot, \cdot \rangle$  should be replaced by H and  $\sigma$ , respectively. It follows from [81] that this  $C^*$ -algebra exists and moreover that it is unique up to isomorphism.

Equation (1.3) defines a representation of  $CCR(\mathbb{H}, \operatorname{Im}\langle \cdot, \cdot \rangle)$  on the Fock space  $\mathcal{F}(\mathbb{H})$ . This representation is the GNS-representation (cf. [75]) with respect to the vacuum state, i.e. the state that maps W(f) to  $\exp(-1/2||f||^2)$ . In Chapter 4 we will encounter GNSrepresentations of  $CCR(\mathbb{H}, \operatorname{Im}\langle \cdot, \cdot \rangle)$  with respect to other states than the vacuum. Given a representation of  $CCR(\mathbb{H}, \operatorname{Im}\langle \cdot, \cdot \rangle)$ , we can define the von Neumann algebra  $\mathcal{W}$  generated by the W(f) ( $f \in \mathbb{H}$ ) represented as operators on the representation Hilbert space. For the vacuum GNS-representation it turns out that  $\mathcal{W}$  is the whole algebra of bounded operators on  $\mathcal{F}(\mathbb{H})$  cf. [75]. The algebra  $\mathcal{W} = \mathcal{B}(\mathcal{F}(\mathbb{H}))$  equipped with the vacuum state is the quantum probability space with which we will describe an electromagnetic field in the vacuum state, see also Section 1.3. More information about CCR-algebras can be found in [25], [26] and [75].

Apart from the Brownian motions  $B_t^{\alpha}$  the algebra  $\mathcal{W} = \mathcal{B}(\mathcal{F}(L^2(\mathbb{R})))$  contains Poisson processes [41], a point that we will investigate below. Let  $P_t : L^2(\mathbb{R}) \to L^2(\mathbb{R})$  denote the projection given by  $f \mapsto \chi_{[0,t)} f$ . The second quantisation of an operator  $A \in \mathcal{B}(L^2(\mathbb{R}))$  is the operator in  $\mathcal{B}(\mathcal{F}(L^2(\mathbb{R})))$  given by

$$\Gamma(A) := 1 \oplus \bigoplus_{n=1}^{\infty} A^{\otimes n}.$$

Then for  $A, B \in \mathcal{B}(L^2(\mathbb{R}))$  we have  $\Gamma(AB) = \Gamma(A)\Gamma(B)$ . This means that the oneparameter group of unitaries generated by  $P_t$ , i.e.  $\exp(isP_t)$ , leads to a one-parameter group of unitaries  $\Gamma(\exp(isP_t))$ . Stone's theorem 1.1.2 asserts the existence of a selfadjoint operator  $\Lambda(t)$  on  $\mathcal{F}(L^2(\mathbb{R}))$  such that for all  $s \in \mathbb{R}$ 

$$\Gamma(\exp(isP_t)) = \exp(is\Lambda(t)).$$

The operator  $\Lambda(t)$  is interpreted as the random variable that counts how many particles, i.e. photons, are present in the interval [0, t).

The family of selfadjoint operators  $\{\Lambda(t); t \geq 0\}$  is commutative, i.e. the bounded operators  $T_+^t := (\Lambda(t) + i)^{-1}$  and  $T_-^t := (\Lambda(t) - i)^{-1}$  generate a commutative von Neumann algebra  $\mathcal{C}$  to which the operators  $\Lambda(t)$  are affiliated. For  $f \in L^2(\mathbb{R})$  a state  $\rho$  on  $\mathcal{C}$  is defined by

$$\rho(C) := \langle \psi(f), C\psi(f) \rangle,$$

where  $\psi(f) \in \mathcal{F}(L^2(\mathbb{R}))$  is the *coherent vector* defined as the exponential vector e(f) normalised to unity

$$\psi(f) := \exp\left(-\frac{1}{2}\|f\|^2\right)e(f).$$

#### 1.2. STOCHASTIC CALCULUS ON FOCK SPACES

The state given by the coherent vector  $\psi(f)$  is the state of the field in a laser beam. Spectral theory provides a probability space  $(\Omega, \Sigma, \mathbb{P})$  such that  $(\mathcal{C}, \rho)$  is isomorphic to  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$ . As before we can realise the selfadjoint operators  $\Lambda(t)$  as measurable functions  $\Lambda(t)_{\bullet}$  on  $\Omega$  taking values in  $\mathbb{R}$ .

For  $s_1 \leq t_1 \leq s_2 \leq t_2$  the characteristic function of the increments  $\Lambda(t_1)_{\bullet} - \Lambda(s_1)_{\bullet}$  and  $\Lambda(t_2)_{\bullet} - \Lambda(s_2)_{\bullet}$  for  $x, y \in \mathbb{R}$  is given by

$$\begin{split} & \mathbb{E}\Big[e^{ix\left(\Lambda(t_{1})\bullet-\Lambda(s_{1})\bullet\right)}e^{iy\left(\Lambda(t_{2})\bullet-\Lambda(s_{2})\bullet\right)}\Big] = \int_{\Omega}e^{ix\left(\Lambda(t_{1})\omega-\Lambda(s_{1})\omega\right)}e^{iy\left(\Lambda(t_{2})\omega-\Lambda(s_{2})\omega\right)}\mathbb{P}(d\omega) = \\ & \left\langle\psi(f), e^{ix\left(\Lambda(t_{1})\omega-\Lambda(s_{1})\omega\right)}e^{iy\left(\Lambda(t_{2})\omega-\Lambda(s_{2})\omega\right)}\psi(f)\right\rangle = \\ & e^{-\|f\|^{2}}\left\langle e(f), \Gamma\left(e^{ix(P_{t_{1}}-P_{s_{1}})}\right)\Gamma\left(e^{iy(P_{t_{2}}-P_{s_{2}})}\right)e(f)\right\rangle = \\ & e^{-\|f\|^{2}}\left\langle e(f), e\left(e^{ix(P_{t_{1}}-P_{s_{1}})}e^{iy(P_{t_{2}}-P_{s_{2}})}f\right)\right\rangle = e^{\left\langle f, \left(e^{ix(P_{t_{1}}-P_{s_{1}})}e^{iy(P_{t_{2}}-P_{s_{2}})}-1\right)f\right\rangle} = \\ & \exp\left(\int_{s_{1}}^{t_{1}}(e^{ix}-1)|f|^{2}d\lambda\right)\exp\left(\int_{s_{2}}^{t_{2}}(e^{iy}-1)|f|^{2}d\lambda\right), \end{split}$$

i.e.  $\{\Lambda(t)_{\bullet}\}_{t\geq 0}$  is a process with independent increments. Moreover, the characteristic function shows that it is a Poisson process with intensity measure  $|f|^2 d\lambda$ , where  $\lambda$  stands for the Lebesgue measure. Summarizing, when photons are counted in a laser beam they arrive Poisson distributed. Since  $\psi(f) = W(f)e(0) = W(f)\Phi$ , we can just as well study the commutative von Neumann algebra  $W(f)^* \mathcal{C}W(f)$ , generated by the operators  $W(f)^* \Lambda(t)W(f)$ , equipped with the vacuum state to arrive again at a Poisson process with intensity measure  $|f|^2 d\lambda$ .

The above exposition shows that the quantum probability space  $(\mathcal{W}, \phi)$  contains many processes that do not commute with each other. Hudson and Parthasarathy showed [54] that it is possible to extend the definition of Itô's stochastic integrals to deal with all these processes simultaneously. To this end we introduce *annihilation* A(t) and *creation operators*  $A^*(t)$  by

$$A(t) := \frac{1}{2} \left( B(i\chi_{[0,t)}) - iB(\chi_{[0,t)}) \right) \quad \text{and} \quad A^*(t) := \frac{1}{2} \left( B(i\chi_{[0,t)}) + iB(\chi_{[0,t)}) \right).$$

Let  $M_t$  stand for one of the three processes A(t),  $A^*(t)$  or  $\Lambda(t)$ , all restricted to the domain  $\mathcal{D}$ . The stochastic integrals will be defined with respect to  $M_t$ .

Let us write  $L^2(\mathbb{R})$  as the direct sum  $L^2((-\infty,t)) \oplus L^2([t,\infty))$ , then  $\mathcal{F}(L^2(\mathbb{R}))$  is unitarily equivalent with  $\mathcal{F}(L^2((-\infty,t))) \otimes \mathcal{F}(L^2([t,\infty)))$  through the identification  $e(f) \cong e(f_t) \otimes e(f_t)$  with  $f_t) := f\chi_{(-\infty,t)}$  and  $f_{[t]} := f\chi_{[t,\infty)}$ . We will also use the notation  $f_{[s,t)}$  for  $f\chi_{[s,t)}$  and omit the tensor product signs between exponential vectors. Furthermore, the algebra  $\mathcal{W} = \mathcal{B}(\mathcal{F}(L^2(\mathbb{R})))$  splits as  $\mathcal{W} = \mathcal{W}_t) \otimes \mathcal{W}_t$  where  $\mathcal{W}_t = \mathcal{B}(\mathcal{F}(L^2((-\infty,t))))$ and  $W_{[t]} = \mathcal{B}(\mathcal{F}(L^2([t,\infty))))$ . The following factorisation property [54], [74] makes the definition of stochastic integration with respect to  $M_t$  possible

$$(M_t - M_s)e(f) = e(f_s) \{ (M_t - M_s)e(f_{[s,t]}) \} e(f_{[t]}),$$

with  $(M_t - M_s)e(f_{[s,t)}) \in \mathcal{F}(L^2([s,t)))$ . We first define the stochastic integral for the so called *simple* operator processes with values in  $\mathcal{B} \otimes \mathcal{W}$ , where  $\mathcal{B}$  is an *n*-dimensional von Neumann algebra called the *initial system*.

**Definition 1.2.1:** Let  $\{L_s\}_{0 \le s \le t}$  be an adapted (i.e.  $L_s \in \mathcal{B} \otimes \mathcal{W}_{s}$ ) for all  $0 \le s \le t$ ) simple process with respect to the partition  $\{s_0 = 0, s_1, \ldots, s_p = t\}$  in the sense that  $L_s = L_{s_j}$  whenever  $s_j \le s < s_{j+1}$ . Then the stochastic integral of L with respect to M on  $\mathbb{C}^n \otimes \mathcal{D}$  is given by [54], [74]:

$$\int_0^t L_s dM_s \ fe(u) := \sum_{j=0}^{p-1} \left( L_{s_j} fe(u_{s_j}) \right) \left( (M_{s_{j+1}} - M_{s_j}) e(u_{[s_j, s_{j+1})}) \right) e(u_{[s_{j+1}}).$$

By the usual approximation by simple processes the definition of the stochastic integral can be extended to a large class of stochastically integrable processes [54], [74]. The notation is simplified by writing  $dX_t = L_t dM_t$  for  $X_t = X_0 + \int_0^t L_s dM_s$ .

The following theorem of Hudson and Parthasarathy [54] extends the Itô rule of classical probability theory.

**Theorem 1.2.2:** (Quantum Itô rule [54], [74]) Let  $M_1$  and  $M_2$  each be one of the processes A(t),  $A^*(t)$  or  $\Lambda(t)$ . Then  $M_1M_2$  is an adapted process satisfying the relation:

$$d(M_1M_2) = M_1 dM_2 + M_2 dM_1 + dM_1 dM_2,$$

where  $dM_1 dM_2$  is given by the quantum Itô table:

$dM_1 \backslash dM_2$	$dA^*(t)$	$d\Lambda(t)$	dA(t)
(U)	0	0	0
$d\Lambda(t)$	$dA^*(t)$	$d\Lambda(t)$	0
dA(t)	dt	dA(t)	0

This theorem will prove to be much more useful in calculations than the actual definition of the stochastic integral. It reduces hard questions regarding analysis to algebraic manipulations with increments  $dA^*(t), dA(t)$  and  $d\Lambda(t)$ .

For a fixed  $\alpha \in [0, \pi)$  we saw that the fields  $B(e^{i\alpha}\chi_{[0,t)})$  define a Brownian motion. Note that from the definition of the creation and annihilation operator (1.2) it follows that

#### 1.3. QUANTUM OPTICS

 $B(e^{i\alpha}\chi_{[0,t)}) = ie^{-i\alpha}A(t) - ie^{i\alpha}A^*(t)$ , i.e.  $dB(e^{i\alpha}\chi_{[0,t)}) = ie^{-i\alpha}dA(t) - ie^{i\alpha}dA^*(t)$ . Therefore, using Theorem 1.2.2,  $\left(dB(e^{i\alpha}\chi_{[0,t)})\right)^2 = dt$ , which is exactly what would be expected for a Brownian motion. Note that in the non-commutative theory we can also calculate products of increments of two non-commuting processes. For instance for  $\alpha_1, \alpha_2 \in [0, \pi)$ ,  $dB(e^{i\alpha_1}\chi_{[0,t)})dB(e^{i\alpha_2}\chi_{[0,t)}) = e^{i(\alpha_2 - \alpha_1)}dt$ .

Let f be an element of  $L^2(\mathbb{R})$ . It is not hard to see (cf. [74]) that the Weyl operator  $W(f_{t}) = \exp\left(A^*(f_t) - A(f_t)\right)$  satisfies the quantum stochastic differential equation

$$dW(f_{t}) = \left\{ f(t)dA^{*}(t) - \overline{f}(t)dA(t) - \frac{1}{2}|f(t)|^{2}dt \right\} W(f_{t}).$$
(1.7)

Denote  $N_t := W(f)^* \Lambda(t) W(f) = W(f_t)^* \Lambda(t) W(f_t)$  then it follows from Theorem 1.2.2 and equation (1.7) that the Poisson process  $N_t$  satisfies [41]

$$dN_t = d\Lambda(t) + f(t)dA^*(t) + \overline{f}(t)dA(t) + |f(t)|^2 dt.$$

It easily follows that  $dN_t^2 = dN_t$ , which is exactly what would be expected for a Poisson process.

## **1.3 Quantum optics**

Quantum optics deals with the interaction between quantum systems and the quantized electromagnetic field. In this section we will point out that in some Markovian approximation this interaction is governed by a stochastic differential equation in the sense of Hudson and Parthasarathy. Indeed, the Markovian approximation is justified if the time scale of the field evolution can be considered to be extremely much faster than the time scale of the quantum system with which it interacts. In this way the field can be considered as a (non-commutative) noise acting on the quantum system.

A convenient starting point (cf. [88], [45]) for quantizing the classical free electromagnetic field is the vector potential  $\boldsymbol{A}(\boldsymbol{r},t)$  in the Coulomb gauge, i.e.  $\nabla \cdot \boldsymbol{A} = 0$ . The magnetic field  $\boldsymbol{B}$  and the electric field  $\boldsymbol{E}$  are determined by  $\boldsymbol{B} = \nabla \times \boldsymbol{A}$  and  $\boldsymbol{E} = -\frac{\partial \boldsymbol{A}}{\partial t}$ , respectively. The Hamiltonian of the free field is given by

$$H = \frac{1}{2} \int \left( \varepsilon_0 \boldsymbol{E}^2 + \frac{1}{\mu_0} \boldsymbol{B}^2 \right) d^3 \boldsymbol{r},$$

where  $\mu_0$  and  $\varepsilon_0$  are the magnetic permeability and electric permittivity of free space, respectively. Then a Fourier expansion of  $\mathbf{A}(\mathbf{r},t)$  is made and  $\mathbf{E}(\mathbf{r},t)$  and  $\mathbf{B}(\mathbf{r},t)$  are expressed in terms of this Fourier expansion. After filling these expressions for  $\mathbf{E}(\mathbf{r},t)$ and  $\mathbf{B}(\mathbf{r},t)$  into the Hamiltonian one easily recognizes the Hamiltonian for an assembly of independent harmonic oscillators, see [88] and [45]. An assembly of quantum harmonic oscillators is described by its algebra of creation and annihilation operators obeying the usual commutation relations, which justifies our description of the quantized electromagnetic field by a CCR-algebra. In this description the electric field of a mode  $g \in L^2(\mathbb{R})$  is given by a polarisation vector times the operator  $i(A(g) - A^*(g))$ , which is just the operator B(g) from the previous section, see also [88], [45].

Let  $\mathcal{B}$  stand for the algebra of observables of an *n*-dimensional quantum system, i.e. the elements of  $\mathcal{B}$  are operators on  $\mathbb{C}^n$ . Let  $\mathcal{W}$  be the von Neumann algebra of observables of the electromagnetic field, i.e. elements of  $\mathcal{W}$  are operators on some representation Hilbert space for the *CCR*-algebra. In the theory of open quantum systems the field  $\mathcal{W}$  is often referred to as the reservoir. The time evolution of the system  $\mathcal{B}$  and the electromagnetic field  $\mathcal{W}$  together is governed by the Hamiltonian H from quantum electrodynamics, cf. [38]. Using shorthand notation  $H_s + H_r := H_s \otimes \mathbf{1}_r + \mathbf{1}_s \otimes H_r$ , we can write this Hamiltonian as

$$H = H_s + H_r + H_{sr},\tag{1.8}$$

where the subscripts s and r stand for the system  $\mathcal{B}$  and the reservoir  $\mathcal{W}$ , respectively. The interaction between system and field is given by the interaction Hamiltonian  $H_{sr}$ .

Let  $\rho$  and  $\gamma$  be states on  $\mathcal{B}$  and  $\mathcal{W}$ , respectively. We can define a time evolved state on  $\mathcal{B} \otimes \mathcal{W}$  by

$$\chi^t(Z) := \rho \otimes \gamma \Big( \exp \Big( \frac{it}{\hbar} H \Big) Z \exp \Big( - \frac{it}{\hbar} H \Big) \Big), \quad Z \in \mathcal{B} \otimes \mathcal{W}, \ t \ge 0.$$

This leads for times  $t \ge 0$  to the following reduced state on system  $\mathcal{B}$ 

$$\rho^t(X) := \chi^t(X \otimes \mathbf{1}_r), \quad X \in \mathcal{B}, \ t \ge 0,$$

and it defines an operation  $T_t^*: \mathcal{B}^* \to \mathcal{B}^*$  for  $t \ge 0$  by  $T_t^*(\rho) := \rho^t$ . The evolution  $T_t$  is still rather complicated, for instance it is not a semigroup, i.e. we do not have  $T_{t+s} = T_t T_s$  for all  $s, t \ge 0$ . We proceed by assuming that  $H_{sr}$  is small compared to  $H_s + H_r$ . We separate the slow evolution generated by  $H_{sr}$  from the rapid evolution generated by  $H_s + H_r$  by transforming to the *interaction picture*, i.e. we define for  $Z \in \mathcal{B} \otimes \mathcal{W}$  and  $X \in \mathcal{B}$ 

$$\tilde{\chi}^{t}(Z) := \chi^{t} \Big( \exp \Big( -\frac{it}{\hbar} (H_{s} + H_{r}) \Big) Z \exp \Big( \frac{it}{\hbar} (H_{s} + H_{r}) \Big) \Big),$$
  

$$\tilde{\rho}^{t}(X) := \tilde{\chi}^{t}(X \otimes \mathbf{1}_{r}) = \rho^{t} \Big( \exp \Big( -\frac{it}{\hbar} H_{s} \Big) X \exp \Big( \frac{it}{\hbar} H_{s} \Big) \Big), \text{ and }$$
  

$$\tilde{H}^{t}_{sr} := \exp \Big( \frac{it}{\hbar} (H_{s} + H_{r}) \Big) H_{sr} \exp \Big( -\frac{it}{\hbar} (H_{s} + H_{r}) \Big).$$

It easily follows that  $\frac{d\tilde{\chi}^t(Z)}{dt} = \frac{i}{\hbar}\tilde{\chi}^t([\tilde{H}_{sr}^t, Z])$  for all  $Z \in \mathcal{B} \otimes \mathcal{W}$ . Expanding this up to second order we find for all  $X \in \mathcal{B}$ 

$$\frac{d\tilde{\rho}^t(X)}{dt} = \frac{i}{\hbar}\rho \otimes \gamma \left( [\tilde{H}_{sr}^t, X \otimes \mathbf{1}_r] \right) - \frac{1}{\hbar^2} \int_0^t \tilde{\chi}^{t'} \left( \left[ \tilde{H}_{sr}^t, [\tilde{H}_{sr}^{t'}, X \otimes \mathbf{1}_r] \right] \right) dt'.$$
(1.9)

We may take  $\frac{i}{\hbar}\rho \otimes \gamma([\tilde{H}_{sr}^t, X \otimes \mathbf{1}_r]) = 0$  in the above equation by including a term  $\mathrm{Id} \otimes \gamma(H_{sr})$  in the system Hamiltonian.

In the coming two paragraphs a heuristic exposition, common in physics, on the so-called *Markov approximation* to equation (1.9), cf. [27], is given. The approximation consists out of two steps. In the first step we replace  $\tilde{\chi}^{t'}$  by  $\tilde{\rho}^{t'} \otimes \gamma$ , and in the second step we replace  $\tilde{\rho}^{t'}$  in its turn by  $\tilde{\rho}^t$ . The first step of the approximation is called the *Born approximation*. It is justified if the reservoir is a very large system, i.e. its state is virtually unaffected by the coupling to  $\mathcal{B}$ , and the coupling between system and reservoir through  $H_{sr}$  is very weak, i.e. at all times  $\chi^t$  shows only deviations of order  $H_{sr}$  from an uncorrelated state, see also [27]. The second step is reasonable if the reservoir correlation times are much shorter than the time scale of the evolution of the system. Then the past history of the system, imprinted in the reservoir through the interaction, can not influence the present state of the system since in the reservoir it gets lost very quickly, see also [27].

After identifying the states  $\tilde{\rho}^t$  and  $\gamma$  with their density matrices, equation (1.9) reduces in the Markov approximation to

$$\frac{d\tilde{\rho}^t}{dt} = -\frac{1}{\hbar^2} \int_0^t \operatorname{Tr}_r \left( \left[ \tilde{H}_{sr}^t, \left[ \tilde{H}_{sr}^{t'}, \tilde{\rho}^t \otimes \gamma \right] \right] \right) dt', \tag{1.10}$$

i.e. it is of the form  $d\tilde{\rho}^t = L^t(\tilde{\rho}^t)dt$ . In many concrete examples, see [27], it can be shown, again by using the fact that the reservoir correlation functions decay extremely much faster than the time scale of the evolution of the system, that the generator  $L^t$  is actually time independent. This means we end up with a time evolution  $T_t^*(\rho) := \tilde{\rho}^t$  that is a one-parameter semigroup, i.e.  $T_tT_s = T_{t+s}$  for all  $t, s \ge 0$ . The semigroup property reflects that there are no memory effects present. The equation  $d\rho^t = L(\rho^t)dt$  is called the *master equation*. The following theorem of Lindblad characterizes the generator of a one-parameter semigroup of operations on  $\mathcal{B} = M_n(\mathbb{C})$ .

**Theorem 1.3.1:** (Lindblad [67]) Let  $\{T_t\}_{t\geq 0}$  be a semigroup of completely positive identity preserving operators on  $M_n(\mathbb{C})$  with generator L. Then there exist a self-adjoint element  $H \in M_n(\mathbb{C})$  and elements  $V_j \in M_n(\mathbb{C})$  for j = 1, 2, ..., k with  $k \leq n^2$ , such that

$$L(X) = i[H, X] + \sum_{j=1}^{k} V_j^* X V_j - \frac{1}{2} \{ V_j^* V_j, X \}, \quad X \in M_n(\mathbb{C}),$$
(1.11)

where  $\{X, Y\}$  stands for the anti-commutator XY + YX. Conversely, every operator L of this form generates a semigroup of completely positive identity preserving operators.

Lindblad's result [67] is actually more general, it is valid for norm-continuous semigroups on the algebra of bounded operators  $\mathcal{B}(\mathbb{H})$  for some, possibly infinite dimensional, Hilbert space  $\mathbb{H}$ . The commutator with H describes the evolution generated by some system Hamiltonian and the part with the  $V_j$ 's describes the decay into the field. The  $V_j$ 's are determined through equation (1.10) and the expression for  $H_{sr}$  in quantum electrodynamics.

Another, more rigorous, approach to the master equation is via the *weak coupling limit*. In this limit the Hamiltonian H of equation (1.8) is replaced by

$$H^{\lambda} = H_s + H_r + \lambda H_{sr}.$$

While the coupling constant  $\lambda$  is sent to 0, the time variable t in the interaction picture has to be scaled to  $\tau := \frac{t}{\lambda^2}$  to compensate the slower decay of the system, i.e. for  $X \in \mathcal{B}$ and  $Z \in \mathcal{B} \otimes \mathcal{W}$  we define

$$\tilde{\rho}_{\lambda}^{t}(X) := \tilde{\chi}_{\lambda}^{\tau}(X \otimes I_{r}), \text{ where } \tilde{\chi}_{\lambda}^{\tau}(Z) := \rho \otimes \gamma \left( U_{\tau}^{\lambda *} Z U_{\tau}^{\lambda} \right), \text{ with} \\ U_{\tau}^{\lambda} := \exp\left(\frac{i\tau}{\hbar} (H_{s} + H_{r})\right) \exp\left(-\frac{i\tau}{\hbar} H^{\lambda}\right).$$

Davies [32] showed that under some technical assumption the time-evolution  $T_t^{\lambda}$ , given by  $T_t^{\lambda*}(\rho) := \tilde{\rho}_{\lambda}^t$ , uniformly converges to a semigroup  $T_t$  when  $\lambda$  goes to 0.

Let us assume that the electromagnetic field is initially in the vacuum state, i.e.  $\gamma = \phi$ . Let  $T_t$  be the semigroup describing the irreversible evolution of the system in the weak coupling limit. Its generator L can be written in the form of equation (1.11). Accardi, Frigerio and Lu showed, see [2], that when  $\lambda$  goes to 0,  $U_{\tau}^{\lambda}$  converges in distribution to the solution  $U_t$  of the quantum stochastic differential equation

$$dU_t = \left\{ V_j dA_j^*(t) - V_j^* dA_j(t) - (iH + \frac{1}{2}V_j^*V_j)dt \right\} U_t,$$

where repeated indices are summed. In this context the weak coupling limit is also called the stochastic limit. Just to support this result, let us check that  $\operatorname{Id} \otimes \phi(U_t^*X \otimes \mathbf{1}_r U_t)$ is the semigroup  $T_t$ . Using the continuous tensor product structure of the Fock space on which  $U_t$  is defined, it is not hard to see that the expression  $\operatorname{Id} \otimes \phi(U_t^*X \otimes \mathbf{1}_r U_t)$  defines a semigroup, i.e. we only have to show that it is generated by L. Since the noises  $A_j$  and  $A_j^*$ are independent for different j and vacuum expectations of  $A_j^*$  and  $A_j$  are zero, it follows from Ito's rules that

$$d\mathrm{Id} \otimes \phi(U_t^* X \otimes \mathbf{1}_r U_t) = \mathrm{Id} \otimes \phi(d(U_t^* X \otimes \mathbf{1}_r U_t)) = \mathrm{Id} \otimes \phi((dU_t^*) X \otimes \mathbf{1}_r U_t) + \mathrm{Id} \otimes \phi(U_t^* X \otimes \mathbf{1}_r dU_t) + \mathrm{Id} \otimes \phi((dU_t^*) X \otimes \mathbf{1}_r dU_t) = (iHX - \frac{1}{2}V_j^* V_j X)dt + (-iXH - \frac{1}{2}XV_j^* V_j)dt + V_j^* XV_j dt = L(X)dt.$$

This result was already obtained by Hudson and Parthasarathy in [54].

In this thesis we will always take the semigroup and its corresponding quantum stochastic differential equation, describing the interaction of the system  $\mathcal{B}$  and the electromagnetic

field  $\mathcal{W}$  in the vacuum, as the starting point. The Markov approximation or the weak coupling limit is a very good approximation for many phenomenon in quantum optics. Barchielli [7] was one of the first to see the relevance of quantum stochastic calculus for quantum optics. See for instance [8] for a description of the electron shelving effect with quantum stochastic calculus. In [76] the Mollow spectrum of fluorescence of a driven two level atom is derived using quantum stochastic calculus.

## **1.4** Filtering and control, outline of results

In this thesis a quantum system  $\mathcal{B}$  in interaction with the electromagnetic field  $\mathcal{W}$  is studied in the weak coupling limit. For simplicity we always assume  $\mathcal{B}$  to be  $M_n(\mathbb{C})$  for some  $n \in \mathbb{N}$ . Next, an observable  $Y_t$  of the field  $\mathcal{W}$  is measured continuously in time. For instance in Chapter 2 the photons emitted into the field by a laser driven two-level atom are counted continuously in time. Since the system  $\mathcal{B}$  interacts with the field  $\mathcal{W}$ , we gain information about the system  $\mathcal{B}$  when the observable  $Y_t$  in the field is measured. For instance, when the field is in the vacuum state we can infer immediately after a photon appears in the field and is counted that the two-level atom is in the ground state. The central question in this thesis is how to condition the state of  $\mathcal{B}$  continuously in time on information gained by measuring some observable  $Y_t$  in the field.

Chapter 2 introduces the subject by analyzing a photon counting experiment, i.e. the observable  $Y_t$  is the photon number operator  $\Lambda(t)$  of the field. The system  $\mathcal{B}$  is a two-level atom driven by a laser. We explicitly write down the solution of the quantum stochastic differential equation using Maassen's integral-sum kernels. The conditioning is done by sandwiching with the projection corresponding to an observed event. In this way a whole family of evolutions for the two-level atom is obtained, i.e. for every possible observed event E in the photon counter there is a map that represents the reduced evolution of the two-level system conditioned on this event E. We prove that this family of maps satisfies the axioms of the processes studied by Davies [31], [33] in the late sixties and early seventies. We use his theory for these processes and the explicit solution, in terms of Maassen's kernels, of the quantum stochastic differential equation to calculate the jump operators that describe the evolution when a photon appears and is detected in the field. This leads to a continuous evolution of the two-level atom interrupted by jumps at the moments at which photons are detected. In quantum optics such an evolution is known as a quantum trajectory [27]. We use the trajectory evolution to show that the photons are detected according to a renewal process.

In Chapter 2 the explicit solution of the quantum stochastic differential equation is used, i.e. we leave the strength of Itô's calculus for increments unused. In Chapter 3 the conditioned evolution of the system  $\mathcal{B}$  is described infinitesimally, fully exploiting the quantum

Itô calculus summarized in Theorem 1.2.2. Some of the ideas of Chapter 2 directly carry over to this description. For every time  $t \ge 0$  there is a measure space  $(\Omega_t, \Sigma_t, \mathbb{P}_t)$  with  $\Omega_t$  the set of all possible paths of the observed process up to time t. In both chapters we are interested in the *consistency* of the family of measures  $\{\mathbb{P}_t\}_{t\ge 0}$ , i.e. for all  $s \ge t$  and  $E \in \Sigma_t : \mathbb{P}_s(E) = \mathbb{P}_t(E)$ . Kolmogorov's extension theorem then states that this family extends to a single probability measure  $\mathbb{P}$  on the paths observed up to infinity.

The conditioning by sandwiching with projections in Chapter 2 is not that easily carried over to the infinitesimal setting of Chapter 3. In the third chapter this is done using the decomposition of a von Neumann algebra  $\mathcal{A}$ , equipped with a normal state  $\chi$  and represented on some Hilbert space  $\mathbb{H}$ , over its center  $\mathcal{C} := \{C \in \mathcal{A}; CA = AC, \forall A \in \mathcal{A}\}$ . Theorem 1.1.1 states that there exists a probability space  $(\Omega, \Sigma, \mathbb{P})$  such that  $(\mathcal{C}, \chi) \cong$  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$ . The decomposition of  $\mathcal{A}$  over  $\mathcal{C}$  described below (see [56] for proofs) is an extension of this result.

The Hilbert space  $\mathbb{H}$  has a direct integral representation  $\mathbb{H} = \int_{\Omega}^{\oplus} \mathbb{H}_{\omega} \mathbb{P}(d\omega)$  [56] in the sense that there exists a family of Hilbert spaces  $\{\mathbb{H}_{\omega}\}_{\omega\in\Omega}$  and for all  $\psi \in \mathbb{H}$  there exists a measurable map  $\omega \mapsto \psi_{\omega} \in \mathbb{H}_{\omega}$  such that

$$\langle \psi, \phi \rangle = \int_{\Omega} \langle \psi_{\omega}, \phi_{\omega} \rangle \mathbb{P}(d\omega), \quad \psi, \phi \in \mathbb{H}.$$

The von Neumann algebra  $\mathcal{A}$  has a central decomposition  $\mathcal{A} = \int_{\Omega}^{\oplus} \mathcal{A}_{\omega} \mathbb{P}(d\omega)$  [56] in the sense that there exists a family  $\{\mathcal{A}_{\omega}\}_{\omega\in\Omega}$  of von Neumann algebras with trivial center, called factors, and for all  $A \in \mathcal{A}$  there exists a measurable map  $\omega \mapsto \mathcal{A}_{\omega} \in \mathcal{A}_{\omega}$  such that  $(A\psi)_{\omega} = \mathcal{A}_{\omega}\psi_{\omega}$  for all  $\psi \in \mathbb{H}$  and for  $\mathbb{P}$ -almost all  $\omega \in \Omega$ . The state  $\chi$  on  $\mathcal{A}$  has a decomposition in states  $\chi_{\omega}$  on  $\mathcal{A}_{\omega}$  [56] such that for all  $A \in \mathcal{A}$  its expectation is given by

$$\chi(A) = \int_{\Omega} \chi_{\omega}(A_{\omega}) \mathbb{P}(d\omega).$$

We think of the state  $\chi$  and an arbitrary operator  $A \in \mathcal{A}$  as maps  $\chi_{\bullet} : \omega \mapsto \chi_{\omega}$  and  $A_{\bullet} : \omega \mapsto A_{\omega}$ , respectively.

Let  $t \geq 0$  and let  $\rho$  be a state on  $\mathcal{B}$ . Define a time evolved state  $\chi^t(Z) := \rho \otimes \phi(U_t^* Z U_t), Z \in \mathcal{B} \otimes \mathcal{W}$  in the interaction picture, with  $U_t$  the solution of the quantum stochastic differential equation describing the interaction between  $\mathcal{B}$  and  $\mathcal{W}$ . Define a commutative algebra  $\mathcal{C}_t$  as the algebra generated by the process  $\{Y_s\}_{s\geq 0}$  up to time t, i.e.  $\mathcal{C}_t$  is generated by the set  $\{Y_s; 0 \leq s \leq t\}$ . Because of the consistency and Kolmogorov's extension theorem there exists an increasing family of  $\sigma$ -algebras  $\{\Sigma_t\}_{t\geq 0}$  such that  $(\mathcal{C}_t, \chi^t) \cong L^{\infty}(\Omega, \Sigma_t, \mathbb{P}_{\rho})$  where  $\Omega$  is the set of all paths of the observed process in the field  $\{Y_s\}_{s\geq 0}$  up to infinity.

We define a subalgebra  $\mathcal{A}_t$  of  $\mathcal{B} \otimes \mathcal{W}$  as the commutant of  $\mathcal{C}_t$ , i.e.  $\mathcal{A}_t := \mathcal{C}'_t$ , and we restrict  $\chi^t$  to this algebra  $\mathcal{A}_t$ . Now  $\mathcal{C}_t$  is the center of  $\mathcal{A}_t$  and we can decompose the state  $\chi^t$  over this center. In this way we get a random state  $\chi^t_{\bullet}$  from  $\Omega$  to the states on  $\mathcal{A}_t$  which for

each  $t \geq 0$  is measurable with respect to  $\Sigma_t$ . Since  $\mathcal{B} \otimes \mathbf{1}_{\mathcal{W}}$  is a subalgebra of  $\mathcal{A}_t$  for all  $t \geq 0$  and since  $(X \otimes \mathbf{1}_{\mathcal{W}})_{\bullet}$  is the constant map  $\omega \mapsto X$ , we obtain a random reduced state  $\rho_{\bullet}^{\bullet}$  from  $\Omega$  to the states on  $\mathcal{B}$  given by

$$\rho^t_{\omega}(X) := \chi^t_{\omega} \big( (X \otimes \mathbf{1}_{\mathcal{W}})_{\omega} \big), \quad \omega \in \Omega, \ X \in \mathcal{B}.$$

The state  $\rho_{\omega}^{t}$  is the state of the system  $\mathcal{B}$  after t seconds of time evolution conditioned on having observed the first t seconds of the path  $\omega$ . The state  $\rho_{E}^{t}$  on  $\mathcal{B}$  after t seconds of time evolution conditioned on some event  $E \in \Sigma_{t}$  is then given by

$$\rho_E^t(X) = \int_E \rho_\omega^t(X) \mathbb{P}_\rho(d\omega), \quad X \in \mathcal{B}.$$

The goal of Chapter 3 is to derive a stochastic differential equation for the state  $\rho_s^t$  in which the stochastic part of the equation is determined by the observed process  $\{Y_s\}_{s\geq 0}$ . As an example, the stochastic differential equation for the two-level atom of Chapter 2 when photons are counted in the field is given by

$$d\rho_{\bullet}^{t}(X) = \rho_{\bullet}^{t} \left( L(X) \right) dt + \left( \frac{\rho_{\bullet}^{t} \left( \mathcal{J}(X) \right)}{\rho_{\bullet}^{t} \left( \mathcal{J}(1) \right)} - \rho_{\bullet}^{t}(X) \right) \left( dN_{t} - \rho_{\bullet}^{t} \left( \mathcal{J}(1) \right) dt \right), \quad X \in \mathcal{B}, \quad (1.12)$$

where L is the Lindblad generator of the semigroup evolution when we would not be counting photons in the field,  $N_t$  is the random variable from  $\Omega \to \mathbb{N}$  that represents the number of photons counted up to time t, and  $\mathcal{J}$  is the jump operation of Chapter 2. The stochastic differential equations derived in Chapter 3 are called *Belavkin equations* [15], [17]. They are known in quantum optics under the somewhat misleading name of *stochastic Schrödinger equations* [27] since they are actually a stochastic variant of a master equation.

Apart from the conditioning for which we use the central decomposition, our derivation of the Belavkin equation is rather close to the original derivation of Belavkin [17]. However, instead of using the explicit construction of the quantum conditional expectation encountered in that derivation, our proofs try to exploit its characterizing properties. Furthermore, we work in the interaction picture, which makes the derivation more accessible.

Let us return to the Belavkin equation, see the example in equation (1.12). It is an equation for the expectation  $\rho_{\bullet}^t(X)$  of some system operator X conditional on the observed process  $Y_t$  in terms of dt and  $dY_t$ . We only have acces to the process  $Y_t$  in the field and since the field is coupled to the system  $\mathcal{B}$  we indirectly gain information on X. This is similar to the situation in classical filter theory, developed mainly by R.L. Stratonovich in the late 1950s, cf. [83], [57]. There one is interested in some system process  $X_t$  but only has access to a process  $Y_t$  which is the system process polluted with some noise. In classical filtering theory one derives a non-linear stochastic differential equation for the conditional expectation of  $X_t$  on the observed process  $Y_t$  in terms of dt and  $dY_t$ , called the filtering equation. The Belavkin equation is a non-commutative analogue of this equation and is therefore some times called the *quantum filtering equation*.

In Chapter 4 a similar setup with a system  $\mathcal{B}$  in interaction with the field  $\mathcal{W}$  is being studied. The problem is to control the state of the system  $\mathcal{B}$ , i.e. we start with an unknown initial state  $\rho$  of the system  $\mathcal{B}$  and then we try to control it in a way that depends on observation of some process  $Y_t$  in the field, aiming to keep the state of the system  $\mathcal{B}$  as close as possible to  $\rho$ . First the case is studied where the stochastic differential equation governing the interaction between  $\mathcal{B}$  and  $\mathcal{W}$  contains only commutative noise terms. This special situation is called *essentially commutative* [63].

To control the state it is first evolved over a time interval  $\tau$  according to the Belavkin equation for the measurement we are performing in the field, i.e.

$$\tilde{\rho}_{\bullet}^{\tau} = \rho^0 + \int_0^{\tau} d\rho_{\bullet}^s,$$

where the tilde is meant to indicate that  $\tilde{\rho}^{\tau}_{\bullet}$  is the state of  $\mathcal{B}$  before control. In the time interval  $\tau$  some measurement result has been obtained for the process observed in the field. We then correct with a unitary  $U_c^{\tau}$  that depends on this result i.e. denoting the state of  $\mathcal{B}$  with its density matrix, we have

$$\rho_{\bullet}^{\tau} = U_c^{\tau} \tilde{\rho}_{\bullet}^{\tau} U_c^{\tau}.$$

We derive a stochastic differential equation for the controlled state evolution depending on the stochastic measurement process. It turns out that in the essentially commutative case it is possible to freeze the state evolution, i.e.  $d\rho_{\bullet}^{t} = 0$ . Such a control scheme is said to restore quantum information [51].

However, the interaction between the system  $\mathcal{B}$  and the field can in general not be treated in an essentially commutative way. For instance, the interaction causing spontaneous decay of a two-level atom into a vacuum field is given by a quantum stochastic differential equation in which the two non-commuting noises  $B_t^0 = B(\chi_{[0,t)})$  and  $B_t^{\pi/2} = B(i\chi_{[0,t)})$  of Section 1.2 appear. The strategy when we are not in the essentially commutative case is to manipulate the field state such that the quantum stochastic differential equation resembles the essentially commutative situation more and more. This can be done by replacing the vacuum state of the field by a squeezed state.

In the vacuum state the variances of  $B_t^0$  and  $B_t^{\pi/2}$  are both equal to t. In a squeezed state the variance of one of these noises is decreased while the other one is increased, since we still have to satisfy Heisenberg's uncertainty relation. The noise with the large variance has the biggest disturbing influence on the evolution of the system  $\mathcal{B}$ , therefore this noise is being observed in the field and the control scheme is based on the measurement results of this observation. It turns out that in the limit for squeezing to infinity the situation where quantum information can be restored is refound.

#### $Abstract^1$

Starting point is a given semigroup of completely positive maps on the  $2 \times 2$  matrices. This semigroup describes the irreversible evolution of a decaying two-level atom. Using the integral-sum kernel approach to quantum stochastic calculus we couple the two-level atom to an environment, the electromagnetic field. The irreversible evolution of the two-level atom stems from the reversible time evolution of atom and field together. Mathematically speaking, we have constructed a Markov dilation of the semigroup.

Next step is to drive the atom by a laser and to count the photons emitted into the field by the decaying two-level atom. For every possible sequence of photon counts a map is constructed that gives the time evolution of the two-level atom inferred by that sequence. This family of maps

<sup>&</sup>lt;sup>1</sup>This chapter is an adapted version of [24].

forms a so-called Davies process. In his book Davies describes the structure of these processes, which brings us into the field of quantum trajectories. Within our model we calculate the jump operators and we briefly describe the resulting counting process.

# 2.1 Introduction

In this paper we want to illustrate that quantum stochastic calculus together with the processes studied by Davies in his book [33], and explained in his paper with Srinivas [82], form a suitable mathematically rigorous framework for doing quantum trajectory theory [27]. As an example we consider here the case of resonance fluorescence.

Our starting point is a semigroup of transition operators  $\{T_t\}_{t\geq 0}$  on the algebra  $M_2$  of all  $2 \times 2$ -matrices. This semigroup describes the irreversible evolution of a spontaneously decaying two-level atom in the Heisenberg picture. By coupling the atom to a quantum noise, we construct a stationary quantum Markov process having precisely these transition operators. If we impose the requirements that the external noise be a Bose field, and the quantum Markov process be minimal, then the latter is uniquely determined. It is called the *minimal Bose dilation* of  $(M_2, T_t, g)$  [60], where g is the ground state of the two-level atom.

Since this dilation is uniquely determined, any other reversible dynamical model which couples  $(M_2, T_t, g)$  to some Bose field necessarily contains this Bose dilation as a subsystem. Therefore, without deriving our model from an explicit Schrödinger equation (by performing a Markovian limit) we may safely assume it to be a physically correct way to describe the interaction of the two-level atom with the electromagnetic field.

We will couple the two-level atom to the electromagnetic field by using quantum stochastic calculus [74], [72]. We use a version of quantum stochastic calculus based on integral-sum kernels [69], [68], [72], which has the advantage that we have an explicit construction for the solution of the quantum stochastic differential equation with which we will describe the coupling of atom and field. Having this explicit construction in our hands is important for doing the actual calculations we encounter later on.

To be able to discuss resonance fluorescence a dilation with two channels in the electromagnetic field is used. On one of them we will put a laser state to drive the two-level atom. We will call this field the *forward channel* and the other one the *side channel*. Then photons are counted in both channels. We need the side channel, because we know that there all detected photons are fluorescence photons. In the forward channel a detected photon could just as well be coming directly from the laser. For every event that can occur in the photon counters a map is constructed that gives the evolution of the two-level atom inferred by that event. We will see that the family of maps we obtain, fulfills the axioms for the processes discussed by Davies [33]. We have constructed the Davies process of resonance fluorescence.

Using the structure theory for Davies processes [33] we can decompose the process into its trajectories [27]. Within our model we calculate the expression for the jump operators and for the time evolution in between jumps. Note that a jump in the system occurs the moment we detect a photon, since our knowledge concerning the system changes. Using the above apparatus we show that the resulting counting process in the side channel is a so-called *renewal process*.

## 2.2 The dilation

Let  $M_2$ , the algebra of  $2 \times 2$ -matrices, stand for the algebra of observables of a twolevel atom. On this algebra we are given a (continuous) semigroup  $\{T_t\}_{t\geq 0}$  of completely positive maps. This semigroup describes the, generally irreversible, evolution of the twolevel atom. Lindblad's Theorem [67] then says that  $T_t = \exp tL$  where  $L: M_2 \to M_2$  can be written as: for  $X \in M_2$ :

$$L(X) = i[H, X] + \sum_{j=1}^{k} V_j^* X V_j - \frac{1}{2} \{ V_j^* V_j, X \},$$
(2.1)

where the  $V_j$  and H are fixed 2 × 2-matrices, H being Hermitian. In this paper we will restrict to the simpler case where H = 0 and there are just two  $V'_js$ . This means there is dissipation only into two channels, the forward channel described by  $V_f$ , and the side channel described by  $V_s$ . We choose  $V_f$  and  $V_s$  such that:

$$V = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad V_f = \kappa_f V, \quad V_s = \kappa_s V, \quad |\kappa_f|^2 + |\kappa_s|^2 = 1$$

This exactly gives the time evolution for spontaneous decay to the ground state of the two-level atom into two decay channels, where the decay rates are given by  $|\kappa_f|^2$  and  $|\kappa_s|^2$ .

We want to see this irreversible evolution of the two-level atom as stemming from a reversible evolution of the atom coupled to, in this case, two decay channels in the field. So let us first construct the algebra of observables for these channels in the field. Let  $\mathcal{F}$  be the symmetric Fock space over the Hilbert space  $L^2(\mathbb{R})$  of square integrable wave functions on the real line, i.e.  $\mathcal{F} := \mathbb{C} \oplus \bigoplus_{n=1}^{\infty} L^2(\mathbb{R})^{\otimes_s n}$ . The electromagnetic field is given by creation and annihilation operators on  $\mathcal{F}$ , generating the algebra of all bounded operators. We need two copies of this algebra, which we denote by  $\mathcal{W}_f$ , which will be the forward channel, and  $\mathcal{W}_s$ , which will be the side channel in the field.

The evolution over a time t of a free field is given by the second quantization of the left shift, i.e. the second quantization of the operator on  $L^2(\mathbb{R})$  which maps  $f(\cdot)$  into  $f(\cdot+t)$ . We denote the second quantization of this operator by  $S_t$ . This means that in the Heisenberg picture we have an evolution on  $\mathcal{W}_f \otimes \mathcal{W}_s$  mapping X into  $(S_t^* \otimes S_t^*)X(S_t \otimes S_t)$   $(= (S_{-t} \otimes S_{-t})X(S_t \otimes S_t))$ , also denoted by  $\mathrm{Ad}[S_t \otimes S_t](X)$ .

The presence of the atom in the field introduces a perturbation on the evolution of the free field. We let this perturbation be given by a certain family of unitary operators  $\{U_t\}_{t\in\mathbb{R}}$ on  $\mathbb{C}^2 \otimes \mathcal{F} \otimes \mathcal{F}$ , to be specified later, that forms a *cocycle* with respect to the shift  $S_t \otimes S_t$ , i.e. for all  $t, s \in \mathbb{R}$ :  $U_{t+s} = (S_{-s} \otimes S_{-s})U_t(S_s \otimes S_s)U_s$ . Given this cocycle, we let the time evolution of the atom and the field together be given by the following one-parameter group  $\{\hat{T}_t\}_{t\in\mathbb{R}}$  (i.e. the evolution is now *reversible*) of \*-automorphisms on  $M_2 \otimes \mathcal{W}_f \otimes \mathcal{W}_s$ : for all  $X \in M_2 \otimes \mathcal{W}_f \otimes \mathcal{W}_s$ :

$$\hat{T}_t(X) = \begin{cases} U_t^{-1}(S_{-t} \otimes S_{-t})X(S_t \otimes S_t)U_t & \text{if } t \ge 0\\ (S_{-t} \otimes S_{-t})U_{-t}XU_{-t}^{-1}(S_t \otimes S_t) & \text{if } t < 0 \end{cases},$$

The solution of the following quantum stochastic differential equation [54], [74] provides us with a cocycle of unitaries with respect to the shift:

$$dU_t = \{V_f dA_{f,t}^* - V_f^* dA_{f,t} + V_s dA_{s,t}^* - V_s^* dA_{s,t} - \frac{1}{2} V^* V dt\} U_t, \quad U_0 = I.$$
(2.2)

In the next section we will give an explicit construction for the solution  $U_t$  of this equation. It can be shown ([54], [40], [69], [74]) that if the cocycle satisfies equation (2.2) we have constructed a so-called quantum Markov dilation  $(M_2 \otimes \mathcal{W}_f \otimes \mathcal{W}_s, \{\hat{T}\}_{t \in \mathbb{R}}, \mathrm{id} \otimes \phi^{\otimes 2})$  of the quantum dynamical system  $(M_2, \{T_t\}_{t \geq 0}, g)$  [59], [60], where  $\phi$  is the vector state on  $\mathcal{W}_{f,s}$ given by the vacuum vector. This means that the following dilation diagram commutes for all  $t \geq 0$  (and that the resulting quantum process is Markov):

i.e. for all  $X \in M_2$ :  $T_t(X) = (\mathrm{Id} \otimes \phi^{\otimes 2}) (\hat{T}_t(X \otimes I^{\otimes 2})).$ 

The diagram can also be read in the Schrödinger picture if we reverse the arrows: start with a state  $\rho$  of the atom  $M_2$  in the upper right hand corner, then this state undergoes the following sequence of maps:

$$\rho \mapsto \rho \otimes \phi^{\otimes 2} \mapsto (\rho \otimes \phi^{\otimes 2}) \circ \hat{T}_t = \hat{T}_{t*}(\rho \otimes \phi^{\otimes 2}) \mapsto \operatorname{Tr}_{\mathcal{F}_f \otimes \mathcal{F}_s} (\hat{T}_{t*}(\rho \otimes \phi^{\otimes 2})).$$

This means that at t = 0, the atom in state  $\rho$  is coupled to the k channels in the vacuum state, and after t seconds of unitary evolution we take the partial trace over the 2 channels.

## 2.3 Guichardet space and integral-sum kernels

Let us now turn to giving the explicit construction for the solution of equation (2.2). For this we need the *Guichardet space*  $\Omega$  [52] of  $\mathbb{R}$ , which is the space of all finite subsets of  $\mathbb{R}$ , i.e.  $\Omega := \bigcup_{n \in \mathbb{N}} \Omega_n$ , where  $\Omega_n := \{\sigma \subset \mathbb{R}; |\sigma| = n\}$ . Let us denote by  $\lambda_n$  the Lebesgue measure on  $\mathbb{R}^n$ . If, for  $n \in \mathbb{N}$ , we let  $j_n : \mathbb{R}^n \to \Omega_n$  denote the map that maps an *n*-tuple  $(t_1, t_2, \ldots, t_n)$  into the set  $\{t_1, t_2, \ldots, t_n\}$ , then we can define a measure  $\mu_n$  on  $\Omega_n$  by:  $\mu_n(E) := \frac{1}{n!} \lambda_n(j_n^{-1}(E))$  for all E in the sigma field  $\Sigma_n$  of  $\Omega_n$  induced by  $j_n$  and the Borel sigma field of  $\mathbb{R}^n$ . Now we define a measure  $\mu$  on  $\Omega$  such that  $\mu(\{\emptyset\}) = 1$  and  $\mu = \mu_n$ on  $\Omega_n$ . This means we have now turned the Guichardet space into the measure space  $(\Omega, \Sigma, \mu)$ .

The key to constructing the solution of equation (2.2) is to identify the symmetric Fock space  $\mathcal{F}$  with the space of all quadratically integrable functions on the Guichardet space  $L^2(\Omega,\mu)$ . To see this identification note that  $L^2(\Omega_n,\mu_n)$  is, in the canonical way, unitarily equivalent with the space of all quadratically integrable functions on  $\mathbb{R}^n$  invariant under permutations of coordinates, denoted  $L^2_{\text{sym}}(\mathbb{R}^n)$ . It is now obvious how to identify  $\mathcal{F} = \mathbb{C} \oplus \bigoplus_{n=1}^{\infty} L^2_{\text{sym}}(\mathbb{R}^n)$  with  $L^2(\Omega,\mu) = \mathbb{C} \oplus \bigoplus_{n=1}^{\infty} L^2(\Omega_n,\mu_n)$ .

For every  $f \in L^2(\mathbb{R})$  we define the *exponential vector*  $e(f) \in \mathcal{F}$  in the following way:  $e(f) := 1 \oplus f \oplus \frac{1}{\sqrt{2}} f^{\otimes 2} \oplus \frac{1}{\sqrt{6}} f^{\otimes 3} \oplus \ldots$  Note that the linear span of all exponential vectors forms a dense subspace of  $\mathcal{F}$ . For every  $f \in L^2(\mathbb{R})$  we define the *coherent vector*  $\psi(f)$  to be the exponential vector of f normalised to unity, i.e.  $\psi(f) = \exp(-\frac{1}{2} \|f\|^2) e(f)$ . Under the above identification of  $\mathcal{F}$  with  $L^2(\Omega, \mu)$ , the exponential vector (of an  $f \in L^2(\mathbb{R})$ ) e(f)is mapped into an element of  $L^2(\Omega, \mu)$  which we denote by  $\pi(f)$  and which is given by:  $\pi(f) : \Omega \to \mathbb{C} : \omega \mapsto \prod_{s \in \omega} f(s)$ , where the empty product  $\prod_{s \in \emptyset} f(s)$  is defined to be 1. We will often choose for f the *indicator function* of a certain interval  $I \subset \mathbb{R}$ , which we denote by  $\chi_I$ . This is the function which is 1 on I and 0 elsewhere.

We are now ready to start the construction of the solution  $U_t$  of equation (2.2). Define the *integral-sum kernel* of  $U_t$  (name will become apparent in a minute) to be the map  $u_t$  that maps four disjoint finite subsets of  $\mathbb{R}$ ,  $\sigma_f$ ,  $\sigma_s$ ,  $\tau_f$ ,  $\tau_s$  (where f and s stand for "forward" and "side") to the following  $2 \times 2$ -matrix, where we write  $\sigma_f \cup \sigma_s \cup \tau_f \cup \tau_s$  also as  $\{t_1, t_2, \ldots, t_k\}$  such that  $t_1 < t_2 < \ldots < t_k$  and  $k \in \mathbb{N}$ :

$$u_t(\sigma_f, \sigma_s, \tau_f, \tau_s) := \pi(\chi_{[0,t]})(\sigma_f \cup \sigma_s \cup \tau_f \cup \tau_s) \exp(-\frac{t - t_k}{2} V^* V) V_k \times \exp(-\frac{t_k - t_{k-1}}{2} V^* V) V_{k-1} \dots V_1 \exp(-\frac{t_1}{2} V^* V),$$

where

$$V_j = \begin{cases} V_f & \text{if } t_j \in \sigma_f \\ -V_f^* & \text{if } t_j \in \tau_f \\ V_s & \text{if } t_j \in \sigma_s \\ -V_s^* & \text{if } t_j \in \tau_s \end{cases}$$

Then we have the following theorem of Maassen, see [69], [68]:

**Theorem 2.3.1:** After identifying  $\mathbb{C}^2 \otimes \mathcal{F} \otimes \mathcal{F}$  with  $L^2_{\mathbb{C}^2}(\Omega \times \Omega, \mu \times \mu)$ , the space of all square integrable functions on  $\Omega \times \Omega$  with values in  $\mathbb{C}^2$ , the solution  $U_t$ :  $L^2_{\mathbb{C}^2}(\Omega \times \Omega, \mu \times \mu) \to L^2_{\mathbb{C}^2}(\Omega \times \Omega, \mu \times \mu)$  of equation (2.2) is given by:

$$(U_t f)(\omega_f, \omega_s) = \sum_{\substack{\sigma_f \subset \omega_f \\ \sigma_s \subset \omega_s}} \int_{\Omega \times \Omega} u_t(\sigma_f, \sigma_s, \tau_f, \tau_s) f\big((\omega_f \setminus \sigma_f) \cup \tau_f, (\omega_s \setminus \sigma_s) \cup \tau_s\big) d\tau_f d\tau_s.$$

Now we have an explicit expression for the time evolution  $\hat{T}_t = \operatorname{Ad}[\hat{U}_t]$ , where  $\hat{U}_t$  is given by  $(S_t \otimes S_t)U_t$  if  $t \geq 0$  and  $U_{-t}^{-1}(S_t \otimes S_t)$  if t < 0. The family  $\{\hat{U}_t\}_{t \in \mathbb{R}}$  forms a group of unitary operators on  $\mathbb{C}^2 \otimes \mathcal{F} \otimes \mathcal{F}$  describing the time evolution of the two-level atom and the two channels in the field together. Stone's Theorem says that there must be a Hamiltonian associated to this time evolution. This Hamiltonian has been calculated recently [50], [49].

## 2.4 The Davies process

We now return to the situation in figure 2.3. We wish to make some changes in this diagram and for this we need to introduce some more notation regarding Guichardet spaces. Let  $I \subset \mathbb{R}$  be an interval. Then the *Guichardet space of* I is the set  $\Omega(I) = \bigcup_{n=0}^{\infty} \Omega_n(I)$ , where  $\Omega_n(I) = \{\sigma \subset I; |\sigma| = n\}$ . In a similar way as for  $\Omega$ , which is  $\Omega(\mathbb{R})$ , we can provide these sets with a measure structure:  $(\Omega(I), \Sigma(I), \mu)$ . Given a subset E of  $\Omega(I)$  in the sigma field  $\Sigma(I)$ , we can construct the projection  $M_{\chi_E}$ :  $L^2(\Omega, \mu) \to L^2(\Omega, \mu)$ :  $f \mapsto \chi_E f$ .

Let I be [-t, 0), then the events in  $\Sigma([-t, 0))$ , which we abbreviate to  $\Sigma_t$ , are events in the output field of the atom up to time t. Remember that the evolution of the free field was given by the left shift and that the atom is sitting in the origin. Since the Guichardet space representation corresponds to the photon number picture, we can give concrete interpretations to the subsets in  $\Sigma_t$ . For instance, the subsets  $\Omega_n([-t, 0))$ , correspond to the events "there are n photons in the output of the atom into this channel of the field up to time t".

Now back to the situation in figure 2.3. Suppose we have been observing the output in

#### 2.4. THE DAVIES PROCESS

the forward and side channel of the atom up to time t with two photon counters. Then we are given two events  $E_f$  and  $E_s$  in  $\Sigma_t$ . Since we know the outcome of the measurements we have to change the time evolution of the two-level atom, i.e. we have to project onto the observed events (see also [9]). This is summarized in the following figure:

where we have suppressed the capital letters M in the projections. The map  $\mathcal{E}_0^t[E_f, E_s]$ :  $M_2 \to M_2$ :  $X \mapsto \mathrm{Id} \otimes \phi^{\otimes 2}(\hat{T}_t(X \otimes \chi_{E_f} \otimes \chi_{E_s}))$  is the unnormalized time evolution of the two-level atom in the Heisenberg picture given that we see event  $E_f$  in the output of the forward channel and event  $E_s$  in the output of the side channel. If we are given a state on  $M_2$ , i.e. a  $2 \times 2$  density matrix  $\rho$ , then the probability of seeing event  $E_f$  in the forward channel and  $E_s$  in the side channel after t seconds of observation is given by:  $\mathbb{P}_{\rho}^t[(E_f, E_s)] = \mathrm{Tr}(\rho \mathcal{E}_0^t[E_f, E_s](I)).$ 

The setting is still not complete for describing resonance fluorescence. Since we are not driving the atom, both the forward and the side channel fields are in the vacuum state, at most one photon can appear in the output. We change this by putting on the forward channel a coherent state with amplitude  $z \in \mathbb{C}$ , defined by:  $\gamma_{z_t} : \mathcal{W} \to \mathbb{C} : X \mapsto \exp(-t|z|^2) \langle \pi(z\chi_{[0,t]}), X\pi(z\chi_{[0,t]}) \rangle$ . Note that  $\gamma_0$  is the vacuum state. Putting a coherent state on the forward channel mimics a laser driving the atom. We have suppressed its oscillations for the sake of simplicity. Now we are ready to do resonance fluorescence, i.e. the diagram has changed into:

$$\begin{array}{cccc} M_2 & \xrightarrow{\mathcal{E}_z^t[E_f, E_s]} & M_2 \\ \mathrm{Id}_{\otimes\chi_{E_f}\otimes\chi_{E_s}} & & & & & & & \\ M_2 \otimes \mathcal{W}_f \otimes \mathcal{W}_s & \xrightarrow{\hat{T}_t} & M_2 \otimes \mathcal{W}_f \otimes \mathcal{W}_s \end{array}$$

where the map  $\mathcal{E}_z^t[E_f, E_s]$ :  $M_2 \to M_2$  is now defined by  $\mathcal{E}_z^t[E_f, E_s](X) := \mathrm{Id} \otimes \gamma_{z_t} \otimes \gamma_0(\hat{T}_t(X \otimes \chi_{E_f} \otimes \chi_{E_s}))$ . It describes the unnormalized time evolution of the laser-driven atom given that we see event  $E_f$  in the output of the forward channel and event  $E_s$  in the output of the side channel. Given a state  $\rho$  of the atom, the probability of seeing event  $E_f$  in the forward channel and  $E_s$  in the side channel after t seconds of observation is now given by:  $\mathbb{P}_\rho^t[(E_f, E_s)] = \mathrm{Tr}(\rho \mathcal{E}_z^t[E_f, E_s](I))$ . To make the notation lighter we suppres the z in  $\mathcal{E}_z^t$  in the following.

Since  $L^2(\Omega, \Sigma, \mu) \otimes L^2(\Omega, \Sigma, \mu)$  is canonically isomorphic to  $L^2(\Omega \times \Omega, \Sigma \otimes \Sigma, \mu \times \mu)$  we can simplify our notation even a bit further. By identifying these spaces we can write  $\mathcal{E}^t[E_f, E_s] = \mathcal{E}^t[E_f \times E_s]$ , where the righthandside is defined by: for all  $E \in \Sigma_t \otimes \Sigma_t, X \in \mathbb{C}$ 

 $M_2, t \ge 0$ :  $\mathcal{E}^t[E](X) := \mathrm{Id} \otimes \gamma_{z_t,0}(\hat{T}_t(X \otimes \chi_E))$ , where  $\gamma_{z_t,0}$  is an abbreviation for  $\gamma_{z_t} \otimes \gamma_0$ . We will now study the properties of the family of maps we defined.

**Theorem 2.4.1:** The family of maps  $\{\mathcal{E}^t[E]\}_{t\geq 0, E\in\Sigma_t\otimes\Sigma_t}$  satisfies the axioms of a Davies process, [33]:

- 1. For all  $t \geq 0$  and  $E \in \Sigma_t \otimes \Sigma_t$ ,  $\mathcal{E}^t[E]$  is completely positive.
- 2. For all  $t \ge 0$  and all countable collections of disjoint sets  $\{E_n\}$  in  $\Sigma_t \otimes \Sigma_t$ and for all  $X \in M_2$ :  $\mathcal{E}^t \Big[ \bigcup_n E_n \Big](X) = \sum_n \mathcal{E}^t [E_n](X).$
- 3. For all  $t \ge 0$  we have  $\mathcal{E}^t \Big[ \Omega \big( [-t, 0) \big) \times \Omega \big( [-t, 0) \big) \Big] (I) = I.$
- 4. For all  $X \in M_2$ :  $\lim_{t\to 0} \mathcal{E}^t \Big[ \Omega \big( [-t,0) \big) \times \Omega \big( [-t,0) \big) \Big] (X) = X.$
- 5. For all  $t, s \ge 0$  and  $E \in \Sigma_s \otimes \Sigma_s, F \in \Sigma_t \otimes \Sigma_t$  and all  $X \in M_2$  we have:  $\mathcal{E}^t[F] \circ \mathcal{E}^s[E](X) = \mathcal{E}^{s+t}[F - s \tilde{\cup} E](X),$ where  $F - s \in \Sigma([-t - s, -s) \otimes \Sigma([-t - s, -s))$  is given by:  $F - s = \{(f_f - s, f_s - s); (f_f, f_s) \in F)\}$  and  $\tilde{\cup}$  is defined by:  $A \tilde{\cup} B = \{(\omega_f \cup \sigma_f, \omega_s \cup \sigma_s); (\omega_f, \omega_s) \in A, (\sigma_f, \sigma_s) \in B\}.$

*Proof.* The only point where there is really something to prove is point 5. Let us first introduce some short notation which we shall only use in this proof. Let  $\pi(z_t, 0)$  denote  $\pi(z\chi_{[0,t]}) \otimes \pi(0)$  and denote  $S_t \otimes S_t$  just by  $S_t$ . Further we use the notation  $\sigma_t(U_s)$  for  $S_{-t}U_sS_t$ . Then for all  $X \in M_2$ ,  $s, t \ge 0$ ,  $E \in \Sigma_s \otimes \Sigma_s$  and  $F \in \Sigma_t \otimes \Sigma_t$  we have:

$$\begin{aligned} \frac{\mathcal{E}^t[F] \circ \mathcal{E}^s[E](X)}{\exp(-(s+t)|z|^2)} &= \mathcal{E}^t[F] \Big( \big\langle \pi(z_s,0), \hat{T}_s(X \otimes \chi_E) \pi(z_s,0) \big\rangle \Big) \exp(t|z|^2) = \\ \big\langle \pi(z_t,0), \hat{T}_t \Big( \big\langle \pi(z_s,0), \hat{T}_s(X \otimes \chi_E) \pi(z_s,0) \big\rangle \otimes \chi_F \Big) \pi(z_t,0) \Big\rangle = \\ \big\langle \pi(z_t,0), U_t^* \big\langle \pi(z_s,0), \hat{T}_s(X \otimes \chi_E) \pi(z_s,0) \big\rangle \otimes \chi_{F+t} U_t \pi(z_t,0) \Big\rangle = \\ \big\langle \pi(z_t,0), U_t^* \big\langle S_{-t}\pi(z_s,0), S_{-t}\hat{T}_s(X \otimes \chi_E) S_t S_{-t}\pi(z_s,0) \big\rangle \otimes \chi_{F+t} U_t \pi(z_t,0) \Big\rangle = \\ \big\langle \pi(z_t,0), U_t^* \big\langle S_{-t}\pi(z_s,0), \sigma_t(U_s)^* X \otimes \chi_{E+t+s} \sigma_t(U_s) S_{-t}\pi(z_s,0) \big\rangle \otimes \chi_{F+t} U_t \pi(z_t,0) \Big\rangle. \end{aligned}$$

Now we use the cocycle identity and the continuous tensor product structure of the symmetric Fock space to obtain:

$$\frac{\mathcal{E}^{t}[F] \circ \mathcal{E}^{s}[E](X)}{\exp(-(s+t)|z|^{2})} = \left\langle \pi(z_{t+s},0), (\sigma_{t}(U_{s})U_{t})^{*}X \otimes \chi_{F+t\tilde{\cup}E+t+s}\sigma_{t}(U_{s})U_{t}\pi(z_{t+s},0) \right\rangle = \left\langle \pi(z_{t+s},0), \hat{T}_{t+s}X \otimes \chi_{F+t\tilde{\cup}E+t+s}U_{t+s}\pi(z_{t+s},0) \right\rangle = \frac{\mathcal{E}^{s+t}[F-s\tilde{\cup}E](X)}{\exp(-(s+t)|z|^{2})}.$$
#### 2.4. THE DAVIES PROCESS

29

Define maps  $Y_t : M_2 \to M_2 : X \mapsto \mathcal{E}^t [\{(\emptyset, \emptyset)\}](X)$ . They represent the evolution of the atom when it is observed that no photons entered the decay channels. Then for all  $t, s \ge 0$ 

$$Y_t Y_s = \mathcal{E}^t \big[ \{ (\emptyset, \emptyset) \} \big] \circ \mathcal{E}^s \big[ \{ (\emptyset, \emptyset) \} \big] = \mathcal{E}^{t+s} \big[ \{ (\emptyset, \emptyset) \} - s \tilde{\cup} \{ (\emptyset, \emptyset) \} \big] = \mathcal{E}^{t+s} \big[ \{ (\emptyset, \emptyset) \} \big] = Y_{t+s},$$

i.e. the family  $\{Y_t\}_{t\geq 0}$  forms a semigroup. Now observe that for  $X\in M_2$  and  $t\geq 0$ 

$$Y_t(X) = \mathcal{E}^t \big[ (\{\emptyset\}, \{\emptyset\}) \big] (X) = \mathrm{Id} \otimes \gamma_{z_t} \otimes \gamma_0 \big( \hat{T}_t(X \otimes \chi_{\{\emptyset\}} \otimes \chi_{\{\emptyset\}}) \big) = \langle \pi(z_t) \otimes \pi(0), U_t^* X \otimes \chi_{\{\emptyset\}} \otimes \chi_{\{\emptyset\}} U_t \pi(z_t) \otimes \pi(0) \rangle \exp(-t|z|^2) = (U_t \pi(z_t) \otimes \pi(0))^* (\emptyset, \emptyset) X \big( U_t \pi(z_t) \otimes \pi(0) \big) (\emptyset, \emptyset) \exp(-t|z|^2),$$

i.e. we can write  $Y_t(X) = B_t^* X B_t$  where  $B_t$  is given by

$$B_t = \left(\exp(-\frac{1}{2}t|z|^2) \left( U_t \pi(z_t) \otimes \pi(0) \right) \right) (\emptyset, \emptyset).$$
(2.4)

Using Theorem 2.3.1 it follows that  $B_t$  is the following semigroup of contractions:

$$B_t = \exp\left(-\frac{1}{2}(|z|^2I_2 + V^*V + 2zV_f^*)t\right),$$

If  $Y_t$  can be written as  $B_t^* \cdot B_t$  for some semigroup of contractions  $B_t$ , the Davies process  $\mathcal{E}^t$  is called *ideal*, see [33].

**Lemma 2.4.2:** The Davies process  $\mathcal{E}^t$  has bounded interaction rate *i.e.* there exists a constant K such that for all  $t \ge 0$ 

$$\mathcal{E}^t \big[ \Omega[-t,0) \times \Omega[-t,0) \setminus \{(\emptyset,\emptyset)\} \big] (I) \le t K I.$$

Proof. From Theorem 2.4.1 point 2 it follows that

$$\mathcal{E}^t \big[ \Omega[-t,0) \times \Omega[-t,0) \setminus \{(\emptyset,\emptyset)\} \big] (I) = I - B_t^* B_t,$$

with  $B_t$  as in equation (2.4). Using Theorem 2.3.1 we find

$$B_t = \exp(-\frac{1}{2}t|z|^2) \begin{pmatrix} \exp(-\frac{t}{2}) & 2z\overline{\kappa}_f(\exp(-\frac{t}{2}) - 1) \\ 0 & 1 \end{pmatrix}.$$

Therefore

$$\mathcal{E}^{t} \begin{bmatrix} \Omega[-t,0) \times \Omega[-t,0) \setminus \{(\emptyset,\emptyset)\} \end{bmatrix} (I) = \\ \begin{pmatrix} 1 - e^{-t(|z|^{2}+1)} & 2z\overline{\kappa}_{f}e^{-t(|z|^{2}+\frac{1}{2})} (1-e^{-\frac{t}{2}}) \\ 2\overline{z}\kappa_{f}e^{-t(|z|^{2}+\frac{1}{2})} (1-e^{-\frac{t}{2}}) & 1 - e^{-t|z|^{2}} (1+4|z|^{2}|\kappa_{f}|^{2} (1-e^{-\frac{t}{2}})^{2}) \end{pmatrix}$$

Since  $\mathcal{E}^t [\Omega[-t, 0) \times \Omega[-t, 0) \setminus \{(\emptyset, \emptyset)\}]$  is completely positive this matrix has to be positive, i.e. its eigenvalues are positive. Let us denote them by  $E_+$  and  $E_-$  such that  $E_+ \ge E_- \ge 0$ . Define  $\alpha := \exp(-t|z|^2)$  and  $\beta := \exp(-\frac{t}{2})$ . Then for all  $t \ge 0$ 

 $\alpha \ge 0, \qquad 1-\beta \ge 0, \qquad 0 \le 1-\alpha \le |z|^2 t, \qquad 0 \le 1-\alpha\beta^2 \le (|z|^2+1)t.$ 

Therefore, for all  $t \ge 0$ 

$$\mathcal{E}^{t} \big[ \Omega[-t,0) \times \Omega[-t,0) \setminus \{(\emptyset,\emptyset)\} \big] (I) \leq E_{+}I \leq (E_{+}+E_{-})I = \operatorname{Tr} \Big( \mathcal{E}^{t} \big[ \Omega[-t,0) \times \Omega[-t,0) \setminus \{(\emptyset,\emptyset)\} \big] (I) \Big) = \big( (1-\alpha\beta^{2}) + (1-\alpha) - 4\alpha |z|^{2} |\kappa_{f}|^{2} (\beta-1)^{2} \big) I \leq \big( (1-\alpha\beta^{2}) + (1-\alpha) \big) I \leq (2|z|^{2}+1)tI.$$

## 2.5 Quantum trajectories

In the seventies Davies studied the structure of what we now call Davies processes [33]. Let us first state his results, as far as relevant, in the context of the process we are studying.

Lemma 2.5.1: (Davies [33]) Given any ideal Davies process  $\mathcal{E}^t$  with bounded interaction rate, as defined in the previous section, we have existence of the following limits:

$$\mathcal{J}_f := \lim_{t \downarrow 0} \frac{1}{t} \mathcal{E}^t \big[ \Omega_1[-t,0), \{\emptyset\} \big] \quad and \quad \mathcal{J}_s := \lim_{t \downarrow 0} \frac{1}{t} \mathcal{E}^t \big[ \{\emptyset\}, \Omega_1[-t,0) \big].$$

These completely positive maps represent the action we have to apply on the two-level atom the moment we see one photon appear in the forward, respectively side channel. They are the *jump operations* for these channels. We will explicitly calculate these limits later on, but first we turn our attention to decomposing the Davies process into its trajectories [27]. For this we need the following definition.

**Definition 2.5.2:** Let  $Y_t : M_2 \to M_2$  be the maps from the previous section, i.e.  $Y_t = \mathcal{E}^t[\{\emptyset\}, \{\emptyset\}]$  and let  $\mathcal{J}_f$  and  $\mathcal{J}_s$  be the maps from lemma 2.5.1. Let  $\omega_f$  and  $\omega_s$  be disjoint elements of  $\Omega[-t, 0)$  and denote  $\omega_f \cup \omega_s$  also as  $\{t_1, \ldots, t_k\}$  where  $-t \leq t_1 < t_2 < \ldots < t_k \leq 0$  for a  $k \in \mathbb{N}$ . Then we define:

$$W_{Y,\mathcal{J}_f,\mathcal{J}_s}(\omega_f,\omega_s) := Y_{t_1+t}\mathcal{J}^{t_1}Y_{t_2-t_1}\mathcal{J}^{t_2}\dots\mathcal{J}^{t_k}Y_{-t_k},$$

where  $\mathcal{J}^{t_i}$  denotes  $\mathcal{J}_s$  if  $t_i \in \omega_s$  and  $\mathcal{J}_f$  if  $t_i \in \omega_f$ .

#### 2.5. QUANTUM TRAJECTORIES

Since  $Y_t$  is the time evolution of the system when, both in the forward and the side channels, no photons are detected and  $\mathcal{J}_f$  and  $\mathcal{J}_s$  are the jump operations that we have to apply when a photon in the corresponding channels appears, it is clear that the string of maps  $Y_{t_1+t}\mathcal{J}^{t_1}Y_{t_2-t_1}\mathcal{J}^{t_2}\ldots\mathcal{J}^{t_k}Y_{-t_k}$  represents the *trajectory* of an observable X in  $M_2$ when we find the outcomes  $\omega_f$  in the forward and  $\omega_s$  in the side channel during our counting experiment. The following theorem of Davies [33] shows how to decompose the Davies process into its trajectories.

**Theorem 2.5.3:** (Davies [33]) Given any ideal Davies process  $\mathcal{E}^t$  with bounded interaction rate, as defined in the previous section, we have for all  $t \ge 0$ ,  $E_f, E_s \in \Sigma_t$  and  $X \in M_2$ :

$$\mathcal{E}^{t}[E_{f}, E_{s}](X) = \int_{E_{f} \times E_{s}} W_{Y, \mathcal{J}_{f}, \mathcal{J}_{s}}(\omega_{f}, \omega_{s})(X) d\mu(\omega_{f}) d\mu(\omega_{s}).$$

In the previous section we already found the expression for the time evolution in between jumps:  $Y_t$ . We now turn to the calculation of  $\mathcal{J}_f$  and  $\mathcal{J}_s$ . For all X in  $M_2$  we have:

$$\mathcal{J}_f(X) = \lim_{t \downarrow 0} \frac{1}{t} \mathcal{E}^t \big[ (\Omega_1[-t,0), \{\emptyset\}) \big](X) = \lim_{t \downarrow 0} \frac{\int_0^t \operatorname{Ad} \big[ U_t \pi(z) \otimes \pi(0)(\{s\}, \emptyset) \big](X) ds}{t \exp(-t|z|^2)}.$$

Now look at  $U_t \pi(z) \otimes \pi(0)(\{s\}, \emptyset)$ , we find by using Theorem 2.3.1:

$$\begin{split} U_t \pi(z) \otimes \pi(0)(\{s\}, \emptyset) &= \sum_{\sigma \subset \{s\}} \int_{\Omega} u_t(\sigma, \emptyset, \tau, \emptyset) z^{1-|\sigma|+|\tau|} d\tau = z u_t(\emptyset, \emptyset, \emptyset, \emptyset) + \\ z^2 \int_0^t u_t(\emptyset, \emptyset, \{r\}, \emptyset) dr &+ u_t(\{s\}, \emptyset, \emptyset, \emptyset) + z \int_0^t u_t(\{s\}, \emptyset, \{r\}, \emptyset) dr + \\ z^2 \int_0^t \int_0^{r_2} u_t(\{s\}, \emptyset, \{r_1, r_2\}, \emptyset) dr_1 dr_2 &= \begin{pmatrix} z \exp(-\frac{t}{2}) & 2z^2 \overline{\kappa}_f \exp(-\frac{t}{2}) - 2z^2 \overline{\kappa}_f \\ \kappa_f \exp(-\frac{s}{2}) & z \end{pmatrix} \end{split}$$

Therefore we get, for all  $X \in M_2$ :

$$\mathcal{J}_f(X) = \lim_{t \downarrow 0} \frac{\int_0^t \operatorname{Ad} \left[ U_t \pi(z) \otimes \pi(0)(\{s\}, \emptyset) \right](X) ds}{t \exp(-t|z|^2)} = \operatorname{Ad} \left[ \begin{pmatrix} z & 0\\ \kappa_f & z \end{pmatrix} \right](X) = \operatorname{Ad}[zI_2 + V_f](X).$$

Let us now turn to the calculation of  $\mathcal{J}_s$ . We find for all  $X \in M_2$ :

$$\mathcal{J}_s(X) = \lim_{t \downarrow 0} \frac{1}{t} \mathcal{E}^t \big[ (\{\emptyset\}, \Omega_1[-t, 0)) \big](X) = \lim_{t \downarrow 0} \frac{\int_0^t \operatorname{Ad} \big[ U_t \pi(z) \otimes \pi(0)(\emptyset, \{s\}) \big](X) ds}{t \exp(-t|z|^2)}$$

Taking a closer look at  $U_t \pi(z) \otimes \pi(0)(\emptyset, \{s\})$ , applying Theorem 2.3.1:

$$U_{t}\pi(z) \otimes \pi(0)(\emptyset, \{s\}) = \int_{\Omega} u_{t}(\emptyset, \{s\}, \tau, \emptyset) z^{|\tau|} d\tau = u_{t}(\emptyset, \{s\}, \emptyset, \emptyset) + z \int_{0}^{t} u_{t}(\emptyset, \{s\}, \{r\}, \emptyset) dr + z^{2} \int_{0}^{t} \int_{0}^{r_{2}} u_{t}(\emptyset, \{s\}, \{r_{1}, r_{2}\}, \emptyset) dr_{1} dr_{2} = \begin{pmatrix} 0 & 0 \\ \kappa_{s} \exp(-\frac{s}{2}) & 0 \end{pmatrix}$$

Therefore we get, for all  $X \in M_2$ :

$$\mathcal{J}_s(X) = \lim_{t \downarrow 0} \frac{\int_0^t \operatorname{Ad} \left[ U_t \pi(z) \otimes \pi(0)(\emptyset, \{s\}) \right](X) ds}{t \exp(-t|z|^2)} = \operatorname{Ad} \left[ \begin{pmatrix} 0 & 0\\ \kappa_s & 0 \end{pmatrix} \right](X) =$$
$$= \operatorname{Ad}[V_s](X).$$

Since we are driving the atom with a laser now, the time evolution when we do not observe the side channel nor the forward channel is now given by

$$T_t^z = \mathcal{E}^t \big[ \Omega[-t, 0), \Omega[-t, 0) \big]$$

and no longer by  $T_t$ . We will now derive the Master equation for this new time evolution. For this we need the Dyson series: let  $L_0$  and J be linear maps from  $M_2 \to M_2$ , then for all  $t \ge 0$ :

$$\exp\left(t(L_0+J)\right) = \int_{\Omega[-t,0)} \exp\left((\omega_1+t)L_0\right) J \exp\left((\omega_2-\omega_1)L_0\right) J \dots J \exp(-\omega_k L_0) d\omega,$$

where we have written  $\omega$  as  $\{\omega_1, \ldots, \omega_k\}$  with  $-t \leq \omega_1 < \ldots < \omega_k \leq 0$ .

Now remember that  $\{Y_t\}_{t\geq 0}$  is a semigroup, i.e. we can write  $Y_t = \exp(tL_0)$ . Then, using Theorem 2.5.3 and twice the Dyson series

$$T_t^z = \mathcal{E}^t \big[ \Omega[-t,0), \Omega[-t,0) \big] = \int_{\Omega[-t,0) \times \Omega[-t,0)} W_{Y,\mathcal{J}_f,\mathcal{J}_s}(\omega_f,\omega_s) d\omega_f d\omega_s = \exp\big(t(L_0 + \mathcal{J}_f + \mathcal{J}_s)\big).$$

This means we get the following Master equation:

$$\frac{d}{dt}T_t^z(\cdot) = (L_0 + \mathcal{J}_f + \mathcal{J}_s)T_t^z(\cdot) = -\frac{1}{2}\{V^*V, T_t^z(\cdot)\} + [zV_f^* - \overline{z}V_f, T_t^z(\cdot)] + V^*T_t^z(\cdot)V,$$
(2.5)

which is exactly the Master equation for resonance fluorescence (see [27]) if we take  $z = -i\frac{\Omega}{2\overline{\kappa}_f}$  with  $\Omega$ , the *Rabi frequency*, real.

In the quantum optics literature (see for instance [27]), usually there is no photon counting measurement done in the forward channel, i.e.  $E_f = \Omega[-t, 0)$ . From here on we will do the

32

#### 2.6. A RENEWAL PROCESS

same, we define for all  $t \ge 0$  and  $E_s \in \Sigma_t$ :  $\mathcal{M}^t[E_s] := \mathcal{E}^t[\Omega[-t,0), E_s]$ . In the following we will also suppress the index s on  $E_s$ . Using the Dyson series and Theorem 2.5.3 we find, for all  $t \ge 0$  and  $E \in \Sigma_t$ :

$$\mathcal{M}^{t}[E] = \int_{E} W_{Z,\mathcal{J}_{s}}(\omega) d\mu(\omega), \qquad (2.6)$$

where the time evolution in between side-channel-jumps  $Z_t$  is given by  $Z_t = \exp(t(L_0 + \mathcal{J}_f))$  and  $W_{Z,\mathcal{J}_s}$  is defined in the obvious way analogous to Definition 2.5.2. Note that we have found exactly the same jump operator and time evolution in between jumps as in the usual quantum optics literature, see for instance [27], [29], i.e. we have succeeded in constructing the Davies process of resonance fluorescence with quantum stochastic calculus.

## 2.6 A renewal process

We will now look briefly at some features of the process  $\mathcal{M}^t$  we obtained. It is easily seen from the fact that  $(\mathcal{J}_s)^2 = 0$  (i.e.  $g_2(0) = 0$ ) that the photons in the side channel arrive *anti-bunched*: the probability to see two photons immediately after each other is 0. We will now show that the photon counting process in the side channel is a so-called *renewal* process.

We denote  $\Sigma^t := \Sigma[0, t)$  and, via a shift, we let events E in  $\Sigma^t$  correspond to events E - tin the output sigma field  $\Sigma_t$ . This means that an element  $\omega = \{\omega_1, \ldots, \omega_k\}$  in  $E \in \Sigma^t$ with  $0 \le \omega_1 < \ldots < \omega_k < t$  should be interpreted as seeing the first photon appear in the side channel at time  $\omega_1$ , the second at time  $\omega_2$  up to the k'th photon at time  $\omega_k$ .

Given that we start the photon counting measurement in the initial state  $\rho$ , we define on the sigma fields  $\Sigma^t$   $(t \ge 0)$  probability measures in the natural way: for  $E \in \Sigma^t$ :  $\mathbb{P}^t_{\rho}[E] := \operatorname{Tr}(\rho \mathcal{M}^t[E-t](I))$ . The family of sigma fields  $\{\Sigma^t\}_{t\ge 0}$  generates a sigma-field  $\Sigma^{\infty}$  of  $\Omega[0,\infty)$ . Using that  $T^z_s(I) = I$ , see equation (2.5), we find for all  $E \in \Sigma^t$ :

$$\mathbb{P}_{\rho}^{t+s}[E] = \operatorname{Tr}\left(\rho\mathcal{M}^{t+s}\left[\left(E\tilde{\cup}\Omega[t,t+s)\right) - (t+s)\right](I)\right) = \operatorname{Tr}\left(\rho\mathcal{M}^{t+s}\left[E - (t+s)\tilde{\cup}\Omega[-s,0)\right](I)\right) = \operatorname{Tr}\left(\rho\mathcal{M}^{t}[E-t]\mathcal{M}^{s}\left[\Omega[-s,0)\right](I)\right) = \operatorname{Tr}\left(\rho\mathcal{M}^{t}[E-t]T_{t}^{z}(I)\right) = \operatorname{Tr}\left(\rho\mathcal{M}^{t}[E-t](I)\right) = \mathbb{P}_{\rho}^{t}[E],$$

i.e.  $\mathbb{P}_{\rho}^{t+s}[E]$  does not depend on s. Therefore the family  $\{\mathbb{P}_{\rho}^{t}\}_{t\geq 0}$  on the sigma-fields  $\{\Sigma^{t}\}_{t\geq 0}$  is consistent, hence by Kolmogorov's extension theorem it extends to a single probability measure  $\mathbb{P}_{\rho}$  on  $\Sigma^{\infty}$ .

In the following, when we write  $\omega \in \Omega[0, \infty)$  as  $\{\omega_1, \omega_2, \ldots\}$ , we imply that  $0 \le \omega_1 < \omega_2 < \ldots$ . For  $j = 1, 2, \ldots$  we define random variables:

$$X_j: \ \Omega[0,\infty) \to \overline{\mathbb{R}}^+: \ \omega = \{\omega_1, \omega_2, \ldots\} \mapsto \begin{cases} \omega_j - \omega_{j-1} & \text{if } |\omega| \ge j \\ \infty & \text{otherwise} \end{cases}$$

where we take  $\omega_0$  to be 0. These random variables give the time elapsed between the (j-1)th and *j*th detection of a photon. To prove that the counting process is a *(modified)* renewal process we have to show that for i = 1, 2, ... the random variables  $X_i$  are independent and for i = 2, 3, ... they are identically distributed. This means we have to show that for i = 2, 3, ... the distribution functions  $F_{X_i}(x) := \mathbb{P}_{\rho}[X_i \leq x]$  are equal and for i, j = 1, 2, ... the joint probability distribution function  $F_{X_i,X_j}(x,y) := \mathbb{P}_{\rho}[X_i \leq x \land X_j \leq y]$  factorizes:  $F_{X_i,X_j}(x,y) = F_{X_i}(x)F_{X_j}(y)$ .

Let us first introduce some convenient notation. Note that, using equation (2.6), we have for all  $E \in \Sigma^t$ :

$$\mathbb{P}_{\rho}[E] = \mathbb{P}_{\rho}^{t}[E] = \operatorname{Tr}\left(\rho \int_{E-t} W_{Z,\mathcal{J}_{s}}(\omega) d\mu(\omega)(I)\right) = \operatorname{Tr}\left(\rho \int_{E} Z_{\omega_{1}}\mathcal{J}_{s}Z_{\omega_{2}-\omega_{1}}\mathcal{J}_{s}\ldots\mathcal{J}_{s}Z_{t-\omega_{k}}(I)d\mu(\omega)\right).$$

We will denote:  $x_1 := \omega_1, x_2 := \omega_2 - \omega_1, \dots, x_{k+1} := t - \omega_k$ , then we can write:

$$\mathbb{P}_{\rho}[E] = \int_{E} \operatorname{Tr}\left(\rho Z_{x_{1}} \mathcal{J}_{s} Z_{x_{2}} \mathcal{J}_{s} \dots \mathcal{J}_{s} Z_{x_{k+1}}(I)\right) d\mu(\omega).$$

Let P denote the matrix  $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ , then we have:

$$\mathcal{J}_{s}Z_{x_{k+1}}(I) = \begin{pmatrix} |\kappa_{s}|^{2} \begin{pmatrix} Z_{x_{k+1}}(I) \end{pmatrix}_{22} & 0 \\ 0 & 0 \end{pmatrix} = |\kappa_{s}|^{2} \begin{pmatrix} Z_{x_{k+1}}(I) \end{pmatrix}_{22} P, \\ \mathcal{J}_{s}Z_{x_{k}}(P) = \begin{pmatrix} |\kappa_{s}|^{2} \begin{pmatrix} Z_{x_{k}}(P) \end{pmatrix}_{22} & 0 \\ 0 & 0 \end{pmatrix} = |\kappa_{s}|^{2} \begin{pmatrix} Z_{x_{k}}(P) \end{pmatrix}_{22} P, \\ \dots \\ \mathcal{J}_{s}Z_{x_{2}}(P) = \begin{pmatrix} |\kappa_{s}|^{2} \begin{pmatrix} Z_{x_{2}}(P) \end{pmatrix}_{22} & 0 \\ 0 & 0 \end{pmatrix} = |\kappa_{s}|^{2} \begin{pmatrix} Z_{x_{2}}(P) \end{pmatrix}_{22} P. \end{pmatrix}$$

Therefore, if we define  $z(x) := |\kappa_s|^2 (Z_x(P))_{22}$ ,  $z_{last}(x) := |\kappa_s|^2 (Z_x(I))_{22}$  and  $z_{first}(x) := \text{Tr}(\rho Z_x(P))$ , we can write (see also [29]):

$$\mathbb{P}_{\rho}[E] = \int_{E} z_{first}(x_1) \Big(\prod_{l=2}^{k} z(x_l)\Big) z_{last}(x_{k+1}) d\mu(\omega).$$
(2.7)

We would like to stress that this formula is only valid for events  $E \in \Sigma^t$  and not for all events in  $\Sigma^{\infty}$ .

#### 2.6. A RENEWAL PROCESS

For  $t \ge 0$  we introduce the following random variables:

$$N_t: \ \Omega[0,\infty) \to \mathbb{N}: \ \omega \mapsto |\omega \cap [0,t]|,$$

counting the number of photons appearing in the side channel up to time t. Since, for strictly positive driving field strengths, i.e. |z| > 0, the eigenvalues of the generator  $L_0 + \mathcal{J}_f$ of the semigroup  $Z_t$  all have strictly negative real parts, we have  $\lim_{t\to\infty} Z_t = 0$ . Using this, formula (2.7) and the fact that the event  $[N_t = 0]$  is an element of  $\Sigma^t$ , we obtain:

$$\lim_{t \to \infty} \mathbb{P}_{\rho}[N_t = 0] = \lim_{t \to \infty} z_{first}(t) = 0.$$

Now suppose we have that  $\lim_{t\to\infty} \mathbb{P}_{\rho}[N_t \leq n] = 0$  for a certain  $n \in \mathbb{N}$ . For  $s \leq t$  we use:  $\mathbb{P}_{\rho}[N_t \leq n+1] = \mathbb{P}_{\rho}[N_t \leq n+1|N_s \leq n]\mathbb{P}_{\rho}[N_s \leq n] + \mathbb{P}_{\rho}[N_t \leq n+1|N_s > n]\mathbb{P}_{\rho}[N_s > n]$ . Therefore we have:

$$\begin{split} &\lim_{t\to\infty} \mathbb{P}_{\rho}[N_t \le n+1] = \lim_{s\to\infty} \lim_{t\to\infty} \mathbb{P}_{\rho}[N_t \le n+1] = \\ &\lim_{s\to\infty} \lim_{t\to\infty} \left( \mathbb{P}_{\rho}[N_t \le n+1|N_s \le n] \mathbb{P}_{\rho}[N_s \le n] + \mathbb{P}_{\rho}[N_t \le n+1|N_s > n] \mathbb{P}_{\rho}[N_s > n] \right) = \\ &\lim_{s\to\infty} \lim_{t\to\infty} \mathbb{P}_{\rho}^t[N_t \le n+1|N_s > n] = \lim_{s\to\infty} \lim_{t\to\infty} z_{last}(t-s) = 0. \end{split}$$

Now using induction, we get for  $n \in \mathbb{N}$ :

$$\lim_{t \to \infty} \mathbb{P}_{\rho}[N_t \le n] = 0.$$

We are now ready to calculate the distribution functions  $F_{X_i}$  and  $F_{X_i,X_j}$ . The problem is that for instance the event  $[X_i \leq x] \in \Sigma^{\infty}$  is not an element of  $\Sigma^t$  for a  $t \in \mathbb{R}$ . We solve this by conditioning on the event  $[N_t \geq i]$  and taking the limit for t to infinity:

$$F_{X_i}(x) = \mathbb{P}_{\rho}[X_i \le x] = \lim_{t \to \infty} \left( \mathbb{P}_{\rho}[X_i \le x | N_t \ge i] \mathbb{P}_{\rho}[N_t \ge i] + \mathbb{P}_{\rho}[X_i \le x | N_t < i] \mathbb{P}_{\rho}[N_t < i] \right) = \lim_{t \to \infty} \mathbb{P}_{\rho}^t[X_i \le x \land N_t \ge i].$$

Now we use again formula (2.7) to obtain for  $i \ge 2$ :

$$F_{X_{i}}(x) = \lim_{t \to \infty} \sum_{k=i}^{\infty} \int_{\sum_{\substack{l=1 \ x_{l} = t}}^{k+1} x_{l} = t} z_{first}(x_{1}) \Big(\prod_{l=2}^{k} z(x_{l})\Big) z_{last}(x_{k+1}) dx_{1} \dots dx_{k+1} = \lim_{t \to \infty} \int_{0}^{x} z(x_{i}) \Big(\sum_{k=i}^{\infty} \int_{\sum_{l \neq i} x_{l} = t-x_{i}}^{\infty} z_{first}(x_{1}) dx_{1} \Big(\prod_{\substack{l=2 \ l \neq i}}^{k} z(x_{l}) dx_{l}\Big) z_{last}(x_{k+1}) dx_{k+1} \Big) dx_{i} = \lim_{t \to \infty} \int_{0}^{x} z(x_{i}) \mathbb{P}_{\rho}^{t-x_{i}} \Big[N_{t-x_{i}} \ge i-1\Big] dx_{i}.$$

Then we use dominated convergence to interchange the limit and the integral to obtain:

$$F_{X_i}(x) = \int_0^x z(x') dx'.$$

When i = 1 we can repeat the whole calculation to find the same result when for z we substitute  $z_{first}$ . It is now obvious that for i = 2, 3, ... the random variables  $X_i$  are identically distributed.

In a similar fashion, only extracting two integrals now, we find that for i, j = 2, 3, ...:  $F_{X_i,X_j}(x,y) = \int_0^x \int_0^y z(x')z(y')dx'dy'$ . If *i* or *j* is 1 we again have to substitute  $z_{first}$  for *z*. It is now obvious that the random variables  $X_i$  and  $X_j$  are independent. We conclude that the family of random variables  $\{X_i\}_{i=1,2,...}$  is a (modified) renewal process.

### $\mathbf{Abstract}^1$

A derivation of Belavkin's stochastic Schrödinger equations is given using quantum filtering theory. We study an open system in contact with its environment, the electromagnetic field. Continuous observation of the field yields information on the system: it is possible to keep track in real time of the best estimate of the system's quantum state given the observations made. This estimate satisfies a stochastic Schrödinger equation, which can be derived from the quantum stochastic differential equation for the interaction picture evolution of system and field together. Throughout the paper we focus on the basic example of resonance fluorescence.

## 3.1 Introduction

It has long been recognized that continuous time measurements can not be described by the standard projection postulate of quantum mechanics. In the late 60's, beginning 70's,

<sup>&</sup>lt;sup>1</sup>This chapter is an adapted version of [23].

Davies developed a theory for continuous time measurement [31] culminating in his book [33]. His mathematical work became known to the quantum optics community through the paper with Srinivas on photon counting [82].

The late 80's brought renewed interest to the theory of continuous time measurement. For instance the waiting time distribution of fluorescence photons of a two-level atom driven by a laser was obtained by associating a continuous evolution to the atom in between photon detections and jumps at the moments a photon is detected [29]. In this way every record of photon detection times determines a trajectory in the state space of the atom. Averaging over all possible detection records leads to the well-known description of the dissipative evolution of the atom by a master equation. Advantage of the trajectory approach is the fact that an initially pure state will remain pure along the whole trajectory. This allows for the use of state vectors instead of density matrices, significantly speeding up computer simulations [73], [30], [44], [27].

Infinitesimally, the quantum trajectories are solutions of a stochastic differential equation with the measurement process as the noise term. The change in the state is given by the sum of two terms: a deterministic one proportional with dt and a stochastic one proportional to the number of detected photons  $dN_t$  in the interval dt. For other schemes such as homodyne detection the corresponding stochastic differential equation is obtained as the diffusive limit of photon counting where the jumps in the state space decrease in size but become increasingly frequent [9], [27], [92]. In this limit the stochastic term in the differential equation is replaced by a process with continuous paths.

The stochastic Schrödinger equations obtained in this way had been postulated before by Gisin [47], [48], [35], [46], in an attempt to generalize the customary unitary evolution in quantum mechanics. The stochastic terms are seen as randomness originating from the measurement process. However, in this approach the correspondence between the different quantum state diffusion equations and the measurements that can be performed is not emphasized.

Another approach originated from the development of quantum stochastic calculus [54], [74], generalizing the classical Itô table to quantum noises represented by creation and annihilation operators (see Section 3.6). Barchielli saw the relevance of this new calculus for quantum optics [7]. Indeed, in the Markovian approximation the interaction between a quantum system and the electromagnetic field is governed by a unitary solution of a quantum stochastic differential equation in the sense of [54].

Belavkin [11] was the first to see the connection between quantum measurement theory and classical filtering theory [57], in which one estimates a signal or system process when observing a function of the signal in the presence of noise. This is done by deriving the filtering equation which is a stochastic differential equation for the expectation value of the system process conditioned on outcomes of the observation process. Belavkin extended the filtering theory [17], [16] to allow for the quantum noises of [54]. Stochastic Schrödinger equations turn out to be examples of the quantum filtering or Belavkin equation [15], [20].

Aim of this paper is to give an elementary presentation of quantum filtering theory. We construct the expectation of an observable conditioned on outcomes of a given measurement process. The differential form of this conditional expectation is the stochastic Schrödinger equation associated with the given measurement. At the heart of the derivation lies the Itô table of quantum stochastic calculus enabling a fast computation of the equation. The procedure is summarized in a small recipe in Section 3.7.

To illustrate the theory we consequently focus on the basic example of resonance fluorescence of a two-level atom for which we consider photon counting and homodyne detection measurement schemes. The stochastic Schrödinger equations for these examples are derived in two ways, once via the usual approach using quantum trajectories and a diffusive limit, and once using quantum filtering theory. In this way we hope to emphasize how conceptually different both methods are.

This paper is organised as follows. Sections 3.2 and 3.3 serve as an introduction to the guiding example of this paper: resonance fluorescence of a two-level atom driven by a laser. In Section 3.2 we put the photon counting description of resonance fluorescence by Davies [24], [29], [28] into the form of a stochastic differential equation driven by the counting process. In Section 3.3 we discuss the homodyne detection scheme as a diffusive limit of the photon counting measurement, arriving at a stochastic differential equation driven by a diffusion process. The equations of Sections 3.2 and 3.3 will be rederived later in a more general way using quantum filtering theory.

In Section 3.4 we introduce the concept of conditional expectation in quantum mechanics by first illustrating it in some simple, motivating examples. Section 3.5 describes the dissipative evolution of the open system within the Markov approximation. The joint evolution of the system and its environment, the quantized electromagnetic field, is given by unitaries satisfying a quantum stochastic differential equation. Given a measurement of some field observables it is shown how to condition the state of the system on outcomes of the measurement using the construction of Section 3.4. Section 3.6 is a short review of quantum stochastic calculus and its applications to open systems. Sections 3.5 and 3.6 describe dilation theory and quantum stochastic calculus in a nutshell.

Section 3.7 contains the derivation of the quantum filtering equation, the stochastic differential equation for the conditional expectation. This equation is the stochastic Schrödinger equation for the given measurement. This part ends with a recipe for computing stochastic Schrödinger equations for a large class of quantum systems and measurements. The end of the article connects to Sections 3.2 and 3.3 by showing how the recipe works in our main example.

## 3.2 The Davies process

We consider a two-level atom in interaction with the quantized electromagnetic field. The state of the atom is described by a  $2 \times 2$ -density matrix  $\rho$ , i.e.  $\rho \ge 0$ , and  $\text{Tr}\rho = 1$ . Atom and field together perform a unitary, thus reversible evolution, but by taking a partial trace over the electromagnetic field we are left with an irreversible, dissipative evolution of the atom alone. In the so called Markov limit it is given by a norm continuous semigroup  $\{T_t\}_{t\ge 0}$  of completely positive maps. A central example discussed in this paper is resonance fluorescence. Here the atom is driven by a laser on the *forward* channel, while in the *side* channel a photon counting measurement is performed. For the time being we will suppress the oscillations of the laser for reasons of simplicity. In this case the Lindblad generator of  $T_t$ , or Liouvillian L is given by (cf. [27]):

$$\frac{d}{dt}\Big|_{t=0} T_t(\rho) = L(\rho) = -i[H,\rho] + i\frac{\Omega}{2}[V+V^*,\rho] - \frac{1}{2}\{V^*V,\rho\} + V\rho V^*, \qquad (3.1)$$

where

$$V = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

 $H := \frac{\omega_0}{2}\sigma_z$  is the Hamiltonian of the atom, and  $\Omega$  is the *Rabi frequency*. The master equation (3.1) can be *unravelled* in many ways depending on what photon detection measurement is performed. By unravelling the master equation we mean writing L as the sum  $\mathcal{L} + \mathcal{J}$ , where  $\mathcal{J}$  represents the instantaneous state change taking place when detecting a photon, and  $\mathcal{L}$  describes the smooth state variation in between these instants.

The unravelling for photon counting in the side channel is given by [27]  

$$\mathcal{L}(\rho) = -i[H,\rho] + i\frac{\Omega}{2}[V+V^*,\rho] - \frac{1}{2}\{V^*V,\rho\} + (1-|\kappa_s|^2)V\rho V^* \text{ and } \mathcal{J}(\rho) = |\kappa_s|^2 V\rho V^*,$$

with  $|\kappa_s|^2$  the decay rate into the side channel.

An outcome of the measurement over an arbitrary finite time interval [0, t) is the set of times  $\{t_1, t_2, \ldots, t_k\}$  at which photons are detected in the side channel of the field. The number of detected photons can be arbitrary, thus the space of outcomes is

$$\Omega\left([0,t)\right) := \bigcup_{n=0}^{\infty} \Omega_n\left([0,t)\right) = \bigcup_{n=0}^{\infty} \{\sigma \subset [0,t); \ |\sigma| = n\}$$

also called the *Guichardet space* [52]. In order to describe the probability distribution of the outcomes we need to make  $\Omega([0,t))$  into a measure space. Let us consider the space of *n*-tuples  $[0,t)^n$  with its Borel  $\sigma$ -algebra and the measure  $\frac{1}{n!}\lambda_n$  where  $\lambda_n$  is the Lebesgue measure. Then the map

$$j_n: [0,t)^n \ni (t_1,\ldots,t_n) \to \{t_1,\ldots,t_n\} \in \Omega_n([0,t))$$

induces the  $\sigma$ -algebra  $\Sigma_n([0,t))$  and the measure  $\mu_n$  on  $\Omega_n([0,t))$ . We define now the measure  $\mu$  on  $\Omega([0,t))$  such that  $\mu(\{\emptyset\}) = 1$  and  $\mu = \mu_n$  on  $\Omega_n([0,t))$ . We will abbreviate

 $\Omega([0,t))$  and  $\Sigma([0,t))$  to  $\Omega^t$  and  $\Sigma^t$ , respectively.

Davies was the first to show [33] (see also [27], [24]) that the unnormalized state of the 2level atom at time t with initial state  $\rho$ , and conditioned on the outcome of the experiment being in a set  $E \in \Sigma^t$  is given by:

$$\mathcal{M}^{t}[E](\rho) = \int_{E} W_{t}(\omega)(\rho) d\mu(\omega),$$

where for  $\omega = \{t_1, \ldots, t_k\} \in \Omega^t$  with  $0 \le t_1 \le \ldots \le t_k < t$  we have

$$W_t(\omega)(\rho) := \exp\left((t-t_k)\mathcal{L}\right)\mathcal{J}\dots\mathcal{J}\exp\left((t_2-t_1)\mathcal{L}\right)\mathcal{J}\exp\left(t_1\mathcal{L}\right)(\rho).$$

Furthermore,  $\mathbb{P}_{\rho}^{t}[E] := \operatorname{Tr}(\mathcal{M}^{t}[E](\rho))$  is the probability that the event E occurs if the initial state is  $\rho$ . The family of prabability measures  $\{\mathbb{P}_{\rho}^{t}\}_{t\geq 0}$  is consistent, i.e.  $\mathbb{P}_{\rho}^{t+s}[E] = \mathbb{P}_{\rho}^{t}[E]$  for all  $E \in \Sigma^{t}, s \geq 0$ , see [24], hence by Kolmogorov's extension theorem it extends to a single probability measure  $\mathbb{P}_{\rho}$  on the  $\sigma$ -algebra  $\Sigma^{\infty}$ , of the set  $\Omega^{\infty}$ .

On the measure space  $(\Omega^{\infty}, \Sigma^{\infty}, \mathbb{P}_{\rho})$  we define the following random variables:

$$N_t: \ \Omega^{\infty} \to \mathbb{N}: \ \omega \mapsto |\omega \cap [0,t)|,$$

counting the number of photons detected in the side channel up to time t. The counting process  $\{N_t\}_{t\geq 0}$  has differential  $dN_t := N_{t+dt} - N_t$  satisfying  $dN_t(\omega) = 1$  if  $t \in \omega$  and  $dN_t(\omega) = 0$  otherwise. Therefore we have the following Itô rules:  $dN_t dN_t = dN_t$  and  $dN_t dt = 0$ , (cf. [9]).

To emphasise the fact that the evolution of the 2-level atom is stochastic, we will regard the normalized density matrix as a random variable  $\{\rho_{\bullet}^t\}_{t\geq 0}$  with values in the 2×2-density matrices defined as follows:

$$\rho_{\bullet}^{t}: \ \Omega^{\infty} \to M_{2}: \ \omega \mapsto \rho_{\omega}^{t} := \frac{W_{t}(\omega \cap [0, t))(\rho)}{\operatorname{Tr}\left(W_{t}(\omega \cap [0, t))(\rho)\right)}.$$
(3.2)

The processes  $N_t$  and  $\rho_{\bullet}^t$  are related through the stochastic differential equation  $d\rho_{\bullet}^t = \alpha_t dt + \beta_t dN_t$ . Following [9] we will now determine the processes  $\alpha_t$  and  $\beta_t$  by differentiating (3.2). If  $t \in \omega$  then  $dN_t(\omega) = 1$ , i.e. the differential dt is negligible compared to  $dN_t = 1$ , therefore:

$$\beta_t(\omega) = \rho_{\omega}^{t+dt} - \rho_{\omega}^t = \frac{\mathcal{J}(\rho_{\omega}^t)}{\operatorname{Tr}(\mathcal{J}(\rho_{\omega}^t))} - \rho_{\omega}^t.$$
(3.3)

On the other hand, if  $t \notin \omega$  then  $dN_t(\omega) = 0$ , i.e.  $dN_t$  is negligible compared to dt. Therefore it is only the dt term that contributes:

$$\alpha_t(\omega) = \frac{d}{ds} \Big|_{s=t} \frac{\exp\left((s-t)\mathcal{L}\right)(\rho_{\omega}^t)}{\operatorname{Tr}\left(\exp\left((s-t)\mathcal{L}\right)(\rho_{\omega}^t)\right)} = \mathcal{L}(\rho_{\omega}^t) - \frac{\rho_{\omega}^t}{\operatorname{Tr}(\rho_{\omega}^t)^2} \operatorname{Tr}\left(\mathcal{L}(\rho_{\omega}^t)\right) = \mathcal{L}(\rho_{\omega}^t) + \operatorname{Tr}\left(\mathcal{J}(\rho_{\omega}^t)\right)\rho_{\omega}^t,$$
(3.4)

where we used that  $\operatorname{Tr}(\mathcal{L}(\rho_{\omega}^{t})) = -\operatorname{Tr}(\mathcal{J}(\rho_{\omega}^{t}))$ , as a consequence of the fact that  $\operatorname{Tr}(L(\sigma)) = 0$  for all density matrices  $\sigma$ . Substituting (3.3) and (3.4) into  $d\rho_{\bullet}^{t} = \alpha_{t}dt + \beta_{t}dN_{t}$  we get the following *stochastic Schrödinger equation* for the state evolution of the 2-level atom if we are counting photons in the side channel (cf. [9], [28], [19]):

$$d\rho_{\bullet}^{t} = L(\rho_{\bullet}^{t})dt + \left(\frac{\mathcal{J}(\rho_{\bullet}^{t})}{\operatorname{Tr}(\mathcal{J}(\rho_{\bullet}^{t}))} - \rho_{\bullet}^{t}\right) \left(dN_{t} - \operatorname{Tr}(\mathcal{J}(\rho_{\bullet}^{t}))dt\right).$$
(3.5)

The differential  $dM_t := dN_t - \text{Tr}(\mathcal{J}(\rho_{\bullet}^t))dt$  and the initial condition  $M_0 = 0$  define an important process  $M_t$  called the *innovating martingale*, discussed in more detail in Section 3.7.

## 3.3 Homodyne detection

We change the experimental setup described in the previous section by introducing a *local* oscillator, i.e. a one mode oscillator in a coherent state given by the normalised vector in  $l^2(\mathbb{N})$ 

$$\psi(\alpha_t) := \exp\left(\frac{-|\alpha_t|^2}{2}\right)(1, \alpha_t, \frac{\alpha_t^2}{\sqrt{2}}, \frac{\alpha_t^3}{\sqrt{6}}, \ldots), \tag{3.6}$$

for a certain  $\alpha_t \in \mathbb{C}$ . We take  $\alpha_t = \frac{w_t}{\varepsilon}$ , where  $w_t$  is a complex number with modulus  $|w_t| = 1$ , and  $\varepsilon > 0$ . The number  $\varepsilon$  is inversely proportional to the intensity of the oscillator. Later on we will let the intensity go to infinity, i.e.  $\varepsilon \to 0$ . The phase  $\phi_t$  of the oscillator is represented by  $w_t = \exp(i\phi_t)$ , with  $\phi_t = \phi_0 + \omega_{lo}t$ , where  $\omega_{lo}$  is the frequency of the oscillator.

The local oscillator is coupled to a channel in the electromagnetic field, the local oscillator beam. The field is initially in the vacuum state. The local oscillator and the field are coupled in such a way that every time a photon is detected in the beam, a jump on the local oscillator occurs, given by the operation

$$\mathcal{J}_{lo}(\rho) = A_{lo}\rho A_{lo}^*,\tag{3.7}$$

where  $A_{lo}$  is the annihilation operator corresponding to the mode of the local oscillator. The coherent state  $\psi(\alpha_t)$  is an eigenstate of the jump operator  $A_{lo}$  at eigenvalue  $\alpha_t$ .

Now we are ready to discuss the homodyne detection scheme. Instead of directly counting photons in the side channel we first mix the side channel with the local oscillator beam with the help of a fifty-fifty beam splitter. In one of the emerging beams a photon counting measurement is performed. A detected photon can come from the atom through the side channel or from the local oscillator via the local oscillator beam. Therefore the jump operator on states  $\sigma$  of the atom and the oscillator together, is the sum of the respective jump operators:

$$\mathcal{J}_{a\otimes lo}(\sigma) = (\kappa_s V \otimes I + I \otimes A_{lo})\sigma(\overline{\kappa}_s V^* \otimes I + I \otimes A_{lo}^*).$$

#### 3.3. HOMODYNE DETECTION

An initial product state  $\rho \otimes |\psi(\alpha_t)\rangle \langle \psi(\alpha_t)|$  of the 2-level atom and the local oscillator will remain a product after the jump since  $\psi(\alpha_t)$  is an eigenvector of the annihilation operator. Tracing out the local oscillator yields the following jump operation for the atom in the homodyne setup:

$$\mathcal{J}_{a}(\rho) = \operatorname{Tr}_{lo}\Big(\mathcal{J}_{a\otimes lo}\big(\rho\otimes \big|\psi(\alpha_{t})\big\rangle\big\langle\psi(\alpha_{t})\big|\big)\Big) = \big(\kappa_{s}V + \frac{w_{t}}{\varepsilon}\big)\rho\big(\overline{\kappa}_{s}V^{*} + \frac{\overline{w}_{t}}{\varepsilon}\big).$$

In the same way as in Section 3.2, we can derive the following stochastic Schrödinger equation for the state evolution of the two-level atom when counting photons after mixing the side channel and the local oscillator beam [9] [28]:

$$d\rho_{\bullet}^{t} = L(\rho_{\bullet}^{t})dt + \frac{1}{\varepsilon} \Big( \frac{\mathcal{J}_{a}(\rho_{\bullet}^{t})}{\operatorname{Tr}(\mathcal{J}_{a}(\rho_{\bullet}^{t}))} - \rho_{\bullet}^{t} \Big) \varepsilon \Big( dN_{t} - \operatorname{Tr}(\mathcal{J}_{a}(\rho_{\bullet}^{t})) dt \Big),$$
(3.8)

where the extra  $\varepsilon$ 's are introduced for future convenience. We will again use the abbreviation:  $dM_t^a = dN_t - \operatorname{Tr}(\mathcal{J}_a(\rho_{\bullet}^t))dt$  for the innovating martingale (see Section 3.7). In the homodyne detection scheme the intensity of the local oscillator beam is taken extremely large, i.e. we are interested in the limit  $\varepsilon \to 0$  [9], [27], [92]. Then the number of detected photons becomes very large and it makes sense to scale and center  $N_t$ , obtaining in this way the process with differential  $dW_t^{\varepsilon} := \varepsilon dN_t - dt/\varepsilon$  and  $W_0^{\varepsilon} = 0$ . We find the following Itô rules for  $dW_t^{\varepsilon}$ :

$$dW_t^{\varepsilon} dW_t^{\varepsilon} = \left(\varepsilon dN_t - \frac{1}{\varepsilon} dt\right) \left(\varepsilon dN_t - \frac{1}{\varepsilon} dt\right) = \varepsilon^2 dN_t = \varepsilon dW_t^{\varepsilon} + dt,$$
  
$$dW_t^{\varepsilon} dt = 0.$$

In the limit  $\varepsilon \to 0$  this becomes  $dW_t dW_t = dt$  and  $dW_t dt = 0$ , i.e. the process  $W_t := \lim_{\varepsilon \to 0} W_t^{\varepsilon}$  is a diffusion. It is actually this scaled and centered process that is being observed and not the individual photon counts  $N_t$ , see [27]. We pass now to the evaluation of the limit of (3.8):

$$\lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \Big( \frac{\mathcal{J}_a(\rho_{\bullet}^t)}{\operatorname{Tr}(\mathcal{J}_a(\rho_{\bullet}^t))} - \rho_{\bullet}^t \Big) = w_t \overline{\kappa}_s \rho_{\bullet}^t V^* + \overline{w}_t \kappa_s V \rho_{\bullet}^t - \operatorname{Tr}(w_t \overline{\kappa}_s \rho_{\bullet}^t V^* + \overline{w}_t \kappa_s V \rho_{\bullet}^t) \rho_{\bullet}^t.$$

This leads to the following stochastic Schrödinger equation for the homodyne detection scheme [9], [28], [92], [19]

$$d\rho_{\bullet}^{t} = L(\rho_{\bullet}^{t})dt + \left(w_{t}\overline{\kappa}_{s}\rho_{\bullet}^{t}V^{*} + \overline{w}_{t}\kappa_{s}V\rho_{\bullet}^{t} - \operatorname{Tr}(w_{t}\overline{\kappa}_{s}\rho_{\bullet}^{t}V^{*} + \overline{w}_{t}\kappa_{s}V\rho_{\bullet}^{t})\rho_{\bullet}^{t}\right)dM_{t}^{hd}, \quad (3.9)$$

for all states  $\rho \in M_2$ , where

$$dM_t^{hd} := dW_t - \operatorname{Tr}(w_t \overline{\kappa}_s \rho_{\bullet}^t V^* + \overline{w}_t \kappa_s V \rho_{\bullet}^t) dt.$$
(3.10)

Let  $a_s(t)$  and  $a_b(t)$  denote the annihilation operators for the side channel and the local oscillator beam, respectively. They satisfy the canonical commutation relations

$$[a_i(t), a_j^*(r)] = \delta_{i,j}\delta(t-r), \quad i, j \in \{s, b\}$$

Smearing with a quadratically integrable function f gives

$$A_i(f) = \int f(t)a_i(t)dt, \quad i \in \{s, b\}.$$

By definition, the stochastic process  $\{N_t\}_{t\geq 0}$  counting the number of detected photons has the same law as the the number operator  $\Lambda(t)$  up to time t for the beam on which the measurement is performed. Formally we can write

$$\Lambda(t) = \int_0^t \left( a_s^*(r) \otimes I + I \otimes a_b^*(r) \right) \left( a_s(r) \otimes I + I \otimes a_b(r) \right) dr.$$

The oscillator beam is at time t in the coherent state  $\psi\left(\frac{f_t}{\varepsilon}\right)$ , where  $f_t \in L^2(\mathbb{R})$  is the function  $r \mapsto w_r \chi_{[0,t]}(r)$ . Since the state of the local oscillator beam is an eigenvector of the annihilation operator  $a_b(r)$ 

$$a_b(r)\psi\left(\frac{f_t}{\varepsilon}\right) = \frac{w_r}{\varepsilon}\psi\left(\frac{f_t}{\varepsilon}\right),$$

we find

$$\varepsilon \Lambda(t) - \frac{t}{\varepsilon} = \varepsilon \Lambda_s(t) \otimes I + \varepsilon \int_0^t \left( \frac{w_r}{\varepsilon} a_s^*(r) + \frac{\overline{w_r}}{\varepsilon} a_s(r) \right) \otimes I + \frac{|w_r|^2}{\varepsilon^2} dr - \frac{t}{\varepsilon}$$
$$= \varepsilon \Lambda_s(t) \otimes I + \left( A_s^*(f_t) + A_s(f_t) \right) \otimes I.$$

The operator  $X_{\phi}(t) := A_s^*(f_t) + A_s(f_t)$  is called a *field quadrature*. We conclude that in the limit  $\varepsilon \to 0$  the homodyne detection is a setup for continuous time measurement of the field quadratures  $X_{\phi}(t)$  of the side channel. (cf. [27]).

## **3.4** Conditional expectations

In the remainder of this article we will derive the equations (3.5) and (3.9) in a different way. We will develop a general way to derive Belavkin equations (or stochastic Schrödinger equations). The counting experiment and the homodyne detection experiment, described in the previous sections, serve as examples in this general framework. The method we describe here closely follows Belavkin's original paper on quantum filtering theory [17]. The construction below, however, uses explicitly the decomposition of operators over the measurement results. In the next section it will turn out that this is done most naturally in the interaction picture.

Let us remind the concept of conditional expectation from probability theory. Let  $(\Omega, \Sigma, \mathbb{P})$  be a probability space describing the "world" and  $\Sigma' \subset \Sigma$  a  $\sigma$ -algebra of events to which

#### 3.4. CONDITIONAL EXPECTATIONS

"we have access". A random variable f on  $(\Omega, \Sigma, \mathbb{P})$  with  $\mathbb{E}(|f|) < \infty$  can be projected to its conditional expectation  $\mathcal{E}(f)$  which is measurable with respect to  $\Sigma'$  and satisfies

$$\int_E f \mathrm{d}\mathbb{P} = \int_E \mathcal{E}(f) \mathrm{d}\mathbb{P}$$

for all events E in  $\Sigma'$ . Our information about the state of that part of the world to which we have access, can be summarized in a probability distribution  $\mathbb{Q}$  on  $\Sigma'$ . Then the predicted expectation of f given this information is  $\int_{\Omega} \mathcal{E}(f) d\mathbb{Q}$ . We will extend this now to quantum systems and measurements.

The guiding example is that of an n level atom described by the algebra  $\mathcal{B} := M_n$  undergoing a transformation given by a completely positive unit preserving map  $T : \mathcal{B} \to \mathcal{B}$  with the following Kraus decomposition  $T(X) = \sum_{i \in \Omega} V_i^* X V_i$ . The elements of  $\Omega$  can be seen as the possible measurement outcomes. For any initial state  $\rho$  of  $\mathcal{B}$  and measurement result  $i \in \Omega$ , the state after the measurement is given by

$$\rho_i = V_i \rho V_i^* / \text{Tr}(V_i \rho V_i^*),$$

and the probability distribution of the outcomes is  $p = \sum_{i \in \Omega} p_i \delta_i$  where  $\delta_i$  is the atomic measure at *i*, and  $p_i = \text{Tr}(V_i \rho V_i^*)$ , which without loss of generality can be assumed to be strictly positive. We represent the measurement by an instrument, that is the completely positive map with the following action on states

$$\mathcal{M}: \ M_n^* \to M_n^* \otimes \ell^1(\Omega): \ \rho \mapsto \sum_{i \in \Omega} \rho_i \otimes p_i \delta_i.$$
(3.11)

Let  $X \in \mathcal{B}$  be an observable of the system. Its expectation after the measurement, given that the result  $i \in \Omega$  has been obtained is  $\text{Tr}(\rho_i X)$ . The function

$$\mathcal{E}(X): \ \Omega \to \mathbb{C}: \ i \mapsto \operatorname{Tr}(\rho_i X)$$

is the conditional expectation of X onto  $\ell^{\infty}(\Omega)$ . If  $q = \sum q_i \delta_i$  is a probability distribution on  $\Omega$  then  $\sum q_i \mathcal{E}(X)(i)$  represents the expectation of X on a statistical ensemble for which the distribution of the measurement outcomes is q. We extend the conditional expectation to the linear map

$$\mathcal{E}: \ \mathcal{B} \otimes \ell^{\infty}(\Omega) \to \ell^{\infty}(\Omega) \subset \mathcal{B} \otimes \ell^{\infty}(\Omega)$$

such that for any element  $A: i \mapsto A_i$  in  $\mathcal{B} \otimes \ell^{\infty}(\Omega) \cong \ell^{\infty}(\Omega \to \mathcal{B})$  we have

$$\mathcal{E}(A): i \mapsto \operatorname{Tr}(\rho_i A_i)$$

This map has the following obvious properties: it is idempotent and has norm one. Moreover, it is the unique linear map with these properties preserving the state  $\mathcal{M}(\rho)$  on  $\mathcal{B} \otimes \ell^{\infty}(\Omega)$ . For this reason we will call  $\mathcal{E}$ , the conditional expectation with respect to  $\mathcal{M}(\rho)$ . Its dual can be seen as an extension of probability distributions  $q \in \ell^{1}(\Omega)$  to states on  $\mathcal{B} \otimes \ell^{\infty}(\Omega)$ 

$$\mathcal{E}^*: \ q \mapsto \sum_{i \in \Omega} \rho_i \otimes q_i \delta_i.$$

Thus while the measurement (3.11) provides a state  $\mathcal{M}(\rho)$  on  $\mathcal{B} \otimes \ell^{\infty}(\Omega)$ , the conditional expectation with respect to  $\mathcal{M}(\rho)$  extends probability distributions  $q \in \ell^1(\Omega)$  of outcomes, to states on  $\mathcal{B} \otimes \ell^{\infty}(\Omega)$ , and in particular on  $\mathcal{B}$  which represents the state after the measurement given the outcomes distribution q.

With this example in mind we pass to a more general setup which will be needed in deriving the stochastic Schrödinger equations. Let  $\mathcal{A}$  be a unital \*-algebra of bounded operators on a Hilbert space  $\mathbb{H}$  whose selfadjoint elements represent the observables of a quantum system. It is natural from the physical point of view to assume that  $\mathcal{A}$  is strongly closed, i.e. if  $\{A_n\}_{n\geq 0}$  is a sequence of operators in  $\mathcal{A}$  such that  $||A_n\psi|| \to ||A\psi||$  for any vector  $\psi$  in  $\mathbb{H}$  and a fixed bounded operator A, then  $A \in \mathcal{A}$ . From the mathematical point of view this leads to the rich theory of von Neumann algebras inspired initially by quantum mechanics, but can as well be seen as the generalization of probability theory to the non-commutative world of quantum mechanics. Indeed, the building blocks of quantum systems are matrix algebras, while probability spaces can be encoded into their *commutative* algebra of bounded random variables  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$  which appeared already in the example above. A state is described by a density matrix in the first case or a probability distribution in the second, in general it is a positive normalized linear functional  $\psi : \mathcal{A} \to \mathbb{C}$ which is continuous with respect to the weak\*-topology, the natural topology on a von Neumann algebra seen as the dual of a Banach space [56].

**Definition 3.4.1:** Let  $\mathcal{B}$  be a von Neumann subalgebra of a von Neumann algebra  $\mathcal{A}$  of operators on a (separable) Hilbert space  $\mathbb{H}$ . A *conditional expectation* of  $\mathcal{A}$  onto  $\mathcal{B}$  is a linear surjective map  $\mathcal{E} : \mathcal{A} \to \mathcal{B}$ , such that:

1.  $\mathcal{E}^2 = \mathcal{E}$  ( $\mathcal{E}$  is idempotent),

2.  $\forall_{A \in \mathcal{A}} : \|\mathcal{E}(A)\| \leq \|A\|$  ( $\mathcal{E}$  is normcontractive).

In [85] it has been shown that the conditions 1 and 2 are equivalent to  $\mathcal{E}$  being an identity preserving, completely positive map, and satisfying the *module property* 

$$\mathcal{E}(B_1 A B_2) = B_1 \mathcal{E}(A) B_2, \quad \text{for all } B_1, B_2 \in \mathcal{B}, \text{ and } A \in \mathcal{A}, \quad (3.12)$$

generalizing a similar property of conditional expectations in classical probability theory (cf. [89]).

In analogy to the classical case we are particularly interested in the conditional expectation which leaves a given state  $\rho$  on  $\mathcal{A}$  invariant, i.e.  $\rho \circ \mathcal{E} = \rho$ . However such a map does not always exist, but if it exists then it is unique [84] and will be denoted  $\mathcal{E}_{\rho}$ . Using  $\mathcal{E}_{\rho}$  we can extend states  $\sigma$  on  $\mathcal{B}$  to states  $\sigma \circ \mathcal{E}_{\rho}$  of  $\mathcal{A}$  which should be interpreted as the updated state of  $\mathcal{A}$  after receiving the information (for instance through a measurement) that the

#### 3.4. CONDITIONAL EXPECTATIONS

subsystem  $\mathcal{B}$  is in the state  $\sigma$  (cf. [62]).

In the remainder of this section we will construct the conditional expectation  $\mathcal{E}_{\rho}$  from a von Neumann algebra  $\mathcal{A}$  onto its *center*  $\mathcal{C} := \{C \in \mathcal{A}; AC = CA \text{ for all } A \in \mathcal{A}\}$  leaving a given state  $\rho$  on  $\mathcal{A}$  invariant. The center  $\mathcal{C}$  is a commutative von Neumann algebra and is therefore isomorphic to some  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$ . In our guiding example the center of  $\mathcal{B} \otimes \ell^{\infty}(\Omega)$  is  $\ell^{\infty}(\Omega)$ . Later on (see section 3.6) this role will be played by the commutative algebra of the observed process with  $\Omega$  the space of all paths of measurement records.

**Theorem 3.4.2:** There exists a unique conditional expectation  $\mathcal{E}_{\rho} : \mathcal{A} \to \mathcal{C}$  which leaves the state  $\rho$  on  $\mathcal{A}$  invariant.

*Proof.* The proof is based on the central decomposition of  $\mathcal{A}$  [56]. In our guiding example,  $\mathcal{B} \otimes \ell^{\infty}(\Omega)$  is isomorphic to  $\oplus_{i \in \Omega} \mathcal{B}_i$  where the  $\mathcal{B}_i$ 's are copies of  $\mathcal{B}$ . In general we can identify the center  $\mathcal{C}$  with some  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$  where  $\mathbb{P}$  corresponds to the restriction of  $\rho$ to  $\mathcal{C}$ . We will ignore for simplicity all issues related with measurability in the following constructions. The Hilbert space  $\mathbb{H}$  has a direct integral representation  $\mathbb{H} = \int_{\Omega}^{\oplus} \mathbb{H}_{\omega} \mathbb{P}(d\omega)$ in the sense that there exists a family of Hilbert spaces  $\{\mathbb{H}_{\omega}\}_{\omega\in\Omega}$  and for any  $\psi \in \mathbb{H}$  there exists a map  $\omega \mapsto \psi_{\omega} \in \mathbb{H}_{\omega}$  such that

$$\langle \psi, \phi \rangle = \int_{\Omega} \langle \psi_{\omega}, \phi_{\omega} \rangle \mathbb{P}(d\omega).$$

The von Neumann algebra  $\mathcal{A}$  has a *central decomposition*  $\mathcal{A} = \int_{\Omega}^{\oplus} \mathcal{A}_{\omega} \mathbb{P}(d\omega)$  in the sense that there exists a family  $\{\mathcal{A}_{\omega}\}_{\omega\in\Omega}$  of von Neumann algebras with trivial center, or factors, and for any  $A \in \mathcal{A}$  there is a map  $\omega \mapsto A_{\omega} \in \mathcal{A}_{\omega}$  such that  $(A\psi)_{\omega} = A_{\omega}\psi_{\omega}$  for all  $\psi \in \mathbb{H}$ and  $\mathbb{P}$ -almost all  $\omega \in \Omega$ . The state  $\rho$  on  $\mathcal{A}$  has a decomposition in states  $\rho_{\omega}$  on  $\mathcal{A}_{\omega}$ such that for any  $A \in \mathcal{A}$  its expectation is obtained by integrating with respect to  $\mathbb{P}$  the expectations of its components  $A_{\omega}$ :

$$\rho(A) = \int_{\Omega} \rho_{\omega}(A_{\omega}) \mathbb{P}(d\omega).$$
(3.13)

The map  $\mathcal{E}_{\rho}$ :  $\mathcal{A} \to \mathcal{C}$  defined by

$$\mathcal{E}_{\rho}(A): \ \omega \mapsto \rho_{\omega}(A_{\omega})$$

for all  $A \in \mathcal{A}$  is the desired conditional expectation. One can easily verify that this map is linear, identity preserving, completely positive (as a positive map onto a commutative von Neumann algebra), and has the module property. Thus,  $\mathcal{E}_{\rho}$  is a conditional expectation and leaves the state  $\rho$  invariant by 3.13. Uniqueness follows from [84].

It is helpful to think of the state  $\rho$  and an arbitrary operator A as maps  $\rho_{\bullet}$ :  $\omega \mapsto \rho_{\omega}$ , and respectively  $A_{\bullet}$ :  $\omega \mapsto A_{\omega}$ . The conditional expectation  $\mathcal{E}_{\rho}(A)$  is the function  $\rho_{\bullet}(A_{\bullet})$ :  $\omega \mapsto \rho_{\omega}(A_{\omega})$ .

## 3.5 The dilation

Let  $\mathcal{B}$  be the observable algebra of a given quantum system on the Hilbert space  $\mathbb{H}$ . In the case of resonance fluorescence  $\mathcal{B}$  will be all  $2 \times 2$  matrices  $M_2$ , the algebra of observables for the 2-level atom. The irreversible evolution of the system in the Heisenberg picture is given by the norm continuous semigroup  $\{T_t\}_{t\geq 0}$  of completely positive maps  $T_t: \mathcal{B} \to \mathcal{B}$ . By Lindblad's theorem [67] we have  $T_t = \exp(tL)$  where the generator  $L: \mathcal{B} \to \mathcal{B}$  has the following action

$$L(X) = i[H, X] + \sum_{j=1}^{k} V_j^* X V_j - \frac{1}{2} \{ V_j^* V_j, X \},$$
(3.14)

where H and the  $V_i$ 's are fixed elements of  $\mathcal{B}$ , H being selfadjoint.

We can see the irreversible evolution as stemming from a *reversible* evolution of the system  $\mathcal{B}$  coupled to an environment, which will be the electromagnetic field. We model a channel in the field by the bosonic or symmetric Fock space over the Hilbert space  $L^2(\mathbb{R})$  of square integrable wave functions on the real line, i.e.

$$\mathcal{F} := \mathbb{C} \oplus \bigoplus_{n=1}^{\infty} L^2(\mathbb{R})^{\otimes_s n}.$$

The algebra generated by the field observables on  $\mathcal{F}$  contains all bounded operators and we denote it by  $\mathcal{W}$ . For the dilation we will need k independent copies of this algebra  $\mathcal{W}^{\otimes k}$ .

The free evolution of the field is given by the unitary group  $S_t$ , the second quantization of the *left* shift s(t) on  $L^2(\mathbb{R})$ , i.e.  $s(t) : f \mapsto f(\cdot + t)$ . In the Heisenberg picture the evolution on  $\mathcal{W}$  is

$$W \mapsto S_t^* W S_t := \operatorname{Ad}[S_t](W)$$

The atom and field together form a closed quantum system, thus their joint evolution is given by a one-parameter group  $\{\hat{T}_t\}_{t\in\mathbb{R}}$  of \*-automorphisms on  $\mathcal{B}\otimes\mathcal{W}^{\otimes k}$ :

$$X \mapsto \hat{U}_t^* X \hat{U}_t := \operatorname{Ad}[\hat{U}_t](X).$$

The group  $\hat{U}_t$  is a perturbation of the free evolution without interaction. We describe this perturbation by the family of unitaries  $U_t := S_{-t}^{\otimes k} \hat{U}_t$  for all  $t \in \mathbb{R}$  satisfying the *cocycle* identity

$$U_{t+s} = S_{-s}^{\otimes k} U_t S_s^{\otimes k} U_s, \quad \text{for all } t, s \in \mathbb{R}.$$

The direct connection between the reduced evolution of the atom given by (3.14) and the cocycle  $U_t$  is one of the important results of quantum stochastic calculus [54] which makes the object of Section 3.6. For the moment we only mention that in the Markov limit,  $U_t$  is the solution of the stochastic differential equation [54], [74], [72]

$$dU_t = \{V_j dA_j^*(t) - V_j^* dA_j(t) - (iH + \frac{1}{2}V_j^*V_j)dt\}U_t, \qquad U_0 = \mathbf{1},$$
(3.15)

where the repeated index j is meant to be summed over. The quantum Markov dilation can be summarized by the following diagram (see [59], [60]):

i.e. for all  $X \in \mathcal{B}$ :  $T_t(X) = (\mathrm{Id} \otimes \phi^{\otimes k})(\hat{T}_t(X \otimes \mathbf{1}^{\otimes k}))$ , where  $\phi$  is the vacuum state on  $\mathcal{W}$ , and  $\mathbf{1}$  is the identity operator in  $\mathcal{W}$ . Any dilation of the semigroup  $T_t$  with Bose fields is unitarily equivalent with the above one under certain minimality requirements. The diagram can also be read in the Schrödinger picture if we reverse the arrows: start with a state  $\rho$  of the system  $\mathcal{B}$  in the upper right hand corner, then this state undergoes the following sequence of maps:

$$\rho \mapsto \rho \otimes \phi^{\otimes k} \mapsto (\rho \otimes \phi^{\otimes k}) \circ \hat{T}_t = \hat{T}_{t*}(\rho \otimes \phi^{\otimes k}) \mapsto \operatorname{Tr}_{\mathcal{F}^{\otimes k}}(\hat{T}_{t*}(\rho \otimes \phi^{\otimes k}))$$

This means that at t = 0, the atom in state  $\rho$  is coupled to the k channels in the vacuum state, and after t seconds of unitary evolution we take the partial trace taken over the k channels.

We would now like to introduce the measurement process. It turns out that this can be best described in the *interaction picture*, where we let the shift part of  $\hat{U}_t = S_t^{\otimes k} U_t$  act on the observables while the cocycle part acts on the states:

$$\rho^t(X) := \rho \otimes \phi^{\otimes k}(U_t^* X U_t) \tag{3.17}$$

for all  $X \in \mathcal{B} \otimes \mathcal{W}^{\otimes k}$ . It is well known that for the Bose field for arbitrary time t we can split the noise algebra as a tensor product

$$\mathcal{W} = \mathcal{W}_{(0)} \otimes \mathcal{W}_{(0,t)} \otimes \mathcal{W}_{[t]}$$

with each term being the algebra generated by those fields over test functions with support in the corresponding subspace of  $L^2(\mathbb{R})$ :

$$L^{2}(\mathbb{R}) = L^{2}((-\infty, 0)) \oplus L^{2}([0, t)) \oplus L^{2}([t, \infty)).$$

Such a continuous tensor product structure is called a *filtration* and it is essential in the development of quantum stochastic calculus reviewed in Section 3.6. The observables which we measure in an arbitrary time interval [0, t) form a commuting family of selfadjoint operators  $\{Y_s\}_{0\leq s\leq t}$  whose spectral projections belong to the middle part of the tensor product  $\mathcal{W}_{[0,t)}$ . In the Davies process  $Y_s = \Lambda(s)$ , i.e. the number operator up to time s, while in the homodyne case  $Y_s = X_{\phi}(s)$ . Notice that the part  $\mathcal{W}_{0}$  will not play any significant role as it corresponds to "what happened before we started our experiment".

Let  $C_t$  be the commutative von Neumann generated by the observed process up to time t,  $\{Y_s\}_{0 \le s \le t}$   $(t \ge 0)$ , seen as a subalgebra of  $\mathcal{B} \otimes \mathcal{W}^{\otimes k}$ . By a theorem on von Neumann algebras,  $C_t$  is equal to the double commutant of the observed process up to time t:  $C_t = \{Y_s; 0 \le s \le t\}''$ , with the commutant  $\mathcal{S}'$  of a subset  $\mathcal{S}$  of  $\mathcal{B} \otimes \mathcal{W}^{\otimes k}$  being defined by  $\mathcal{S}' := \{X \in \mathcal{B} \otimes \mathcal{W}^{\otimes k}; XS = SX \forall S \in \mathcal{S}\}$ . The algebras  $\{C_t\}_{t\ge 0}$  form a growing family, that is  $C_s \subset C_t$  for all  $s \le t$ . Thus we can define the inductive limit  $\mathcal{C}_{\infty} := \lim_{t\to\infty} \mathcal{C}_t$ , which is the smallest von Neumann algebra containing all  $\mathcal{C}_t$ . On the other hand for each  $t \ge 0$  we have a state on  $\mathcal{C}_t$  given by the restriction of the state  $\rho^t$  of the whole system defined by (3.17). We will show now that the states  $\rho^t$  for different times "agree with each other".

**Theorem 3.5.1:** On the commutative algebra  $\mathcal{C}_{\infty}$  there exists a unique state  $\rho^{\infty}$  which coincides with  $\rho^t$  when restricted to  $\mathcal{C}_t \subset \mathcal{C}_{\infty}$ , for all  $t \geq 0$ . In particular there exists a measure space  $(\Omega, \Sigma, \mathbb{P}_{\rho})$  such that  $(\mathcal{C}_{\infty}, \rho^{\infty})$  is isomorphic with  $L^{\infty}(\Omega, \Sigma, \mathbb{P}_{\rho})$  and a growing family  $\{\Sigma_t\}_{t>0}$  of  $\sigma$ -subalgebras of  $\Sigma$  such that  $(\mathcal{C}_t, \rho^t) \cong L^{\infty}(\Omega, \Sigma_t, \mathbb{P}_{\rho})$ .

Proof. In the following we will drop the extensive notation of tensoring identity operators when representing operators in  $\mathcal{W}_{[s,t)}$  for all  $s, t \in \mathbb{R}$ . Let  $X \in \mathcal{C}_s$ , in particular  $X \in \mathcal{W}_{[0,s)}^{\otimes k}$ . By (3.15),  $U_t \in \mathcal{B} \otimes \mathcal{W}_{[0,t)}^{\otimes k}$ , because the coefficients of the stochastic differential equation lie in  $\mathcal{B} \otimes \mathcal{W}_{[0,t)}^{\otimes k}$ . This implies that  $S_{-s}^{\otimes k} U_t S_s^{\otimes k} \in \mathcal{B} \otimes \mathcal{W}_{[s,t+s)}^{\otimes k}$ . Using the tensor product structure of  $\mathcal{W}^{\otimes k}$ , we see that  $\mathcal{W}_{[0,s)}^{\otimes k}$  and  $\mathcal{B} \otimes \mathcal{W}_{[s,t+s)}^{\otimes k}$  commute, and in particular Xcommutes with  $S_{-s}^{\otimes k} U_t S_s^{\otimes k}$ . Then

$$\rho^{t+s}(X) = \rho^0(U_{t+s}^* X U_{t+s}) = \rho^0(U_s^* (S_{-s}^{\otimes k} U_t S_s^{\otimes k})^* X S_{-s}^{\otimes k} U_t S_s^{\otimes k} U_s) 
= \rho^0(U_s^* X U_s) = \rho^s(X).$$
(3.18)

This implies that the limit state  $\rho^{\infty}$  on  $\mathcal{C}_{\infty}$  with the desired properties exists, in analogy to the Kolmogorov extension theorem for probability measures. As seen in the previous section,  $(\mathcal{C}_{\infty}, \rho^{\infty})$  is isomorphic to  $L^{\infty}(\Omega, \Sigma, \mathbb{P}_{\rho})$  for some probability space  $(\Omega, \Sigma, \mathbb{P}_{\rho})$ . The subalgebras  $(\mathcal{C}_t, \rho^t)$  are isomorphic to  $L^{\infty}(\Omega, \Sigma_t, \mathbb{P}_{\rho})$  for some growing family  $\{\Sigma_t\}_{t\geq 0}$  of  $\sigma$ -subalgebras of  $\Sigma$ .

**Remark.** From spectral theory it follows that the measure space  $(\Omega^t, \Sigma_t)$  coincides with the joint spectrum of  $\{Y_s\}_{s \leq t}$ , i.e.  $\Omega^t$  is the set of all paths of the process up to time t. For the example of the counting process this means that  $\Omega^t$  is the Guichardet space of the interval [0, t), which is the set of all sets of instants representing a "click" of the photon counter, i.e. it is the set of all paths of the counting process.

We define now  $\mathcal{A}_t := \mathcal{C}'_t$  for all  $t \ge 0$ , i.e.  $\mathcal{A}_t$  is the commutant of  $\mathcal{C}_t$ , then  $\mathcal{C}_t$  is the center of the von Neumann algebra  $\mathcal{A}_t$ . Notice that the observable algebra of the atom  $\mathcal{B}$  is contained in  $\mathcal{A}_t$ . By Theorem 3.4.2 we can construct a family of conditional expectations  ${\mathcal{E}_{\rho^t}^t : \mathcal{A}_t \to \mathcal{C}_t}_{t\geq 0}$ . For each  $t, \mathcal{E}_{\rho^t}^t$  depends on the state of the "world" at that moment  $\rho^t$ , keeping this in mind we will simply denote it by  $\mathcal{E}^t$ . An important property of  $\mathcal{E}^t$  is that  $\rho^{\infty} \circ \mathcal{E}^t = \rho^t \circ \mathcal{E}^t = \rho^t$ , since the range of  $\mathcal{E}^t$  is  $\mathcal{C}_t$  and  $\mathcal{E}^t$  leaves  $\rho^t$  invariant.

For an element  $X \in \mathcal{A}_t$ ,  $\mathcal{E}^t(X)$  is an element in  $\mathcal{C}_t$ , i.e. a function on  $\Omega_t$ . Its value in a point  $\omega \in \Omega_t$ , i.e. an outcomes record up to time t, is the expectation value of X given the observed path  $\omega$  after t time units. We will use the notation  $\mathcal{E}^t(X) := \rho_{\bullet}^t(X_{\bullet})$  defined in the end of Section 3.4 to emphasise the fact that this is a function on  $\Omega_t$ . When restricted to  $\mathcal{B} \otimes \mathcal{C}_t$  the conditional expectation is precisely of the type discussed in our guiding example in Section 3.4.

There exists no conditional expectation from  $\mathcal{B} \otimes \mathcal{W}$  onto  $\mathcal{C}_t$  since performing the measurement has *demolished* the information about observables that do not commute with the observed process [17]. We call  $\mathcal{A}_t$  the algebra of observables that are *not demolished* [17] by observing the process  $\{Y_s\}_{0 \leq s \leq t}$ . This means that performing the experiment and ignoring the outcomes gives the same time evolution on  $\mathcal{A}_t$  as when no measurement was done.

From classical probability it follows that for all  $t \geq 0$  there exists a unique conditional expectation  $\mathbb{E}_{\rho}^{t} : \mathcal{C}_{\infty} \to \mathcal{C}_{t}$  that leaves the state  $\rho^{\infty}$  invariant, i.e.  $\rho^{\infty} \circ \mathbb{E}_{\rho}^{t} = \rho^{\infty}$ . These conditional expectations have the *tower property*, i.e.  $\mathbb{E}_{\rho}^{s} \circ \mathbb{E}_{\rho}^{t} = \mathbb{E}_{\rho}^{s}$  for all  $t \geq s \geq 0$ , which is often very useful in calculations.  $\mathbb{E}_{\rho}^{0}$  is the expectation with respect to  $\mathbb{P}_{\rho}$ , and will simply be denoted  $\mathbb{E}_{\rho}$ . Note that the tower property for s = 0 is exactly the invariance of the state  $\rho^{\infty}(=\mathbb{E}_{\rho})$ .

## 3.6 Quantum stochastic calculus

In this section we briefly discuss the quantum stochastic calculus developed by Hudson and Parthasarathy [54]. For a detailed treatment of the subject we refer to [74] and [72]. Let  $\mathcal{F}(\mathcal{H})$  denote the symmetric (or bosonic) Fock space over the one particle space  $\mathcal{H} := \mathbb{C}^k \otimes L^2(\mathbb{R}_+) = L^2(\{1, 2, \ldots, k\} \times \mathbb{R}_+)$ . The space  $\mathbb{C}^k$  describes the k channels we identified in the electromagnetic field. As in the previous section we denote the algebra of bounded operators on the one channel Fock space  $\mathcal{F}(\mathbb{R}_+)$  by  $\mathcal{W}$ , and on the k channels  $\mathcal{F}(\mathcal{H})$  by  $\mathcal{W}^{\otimes k}$ .

For every  $f \in \mathcal{H}$  we define the *exponential vector*  $e(f) \in \mathcal{F}(\mathcal{H})$  in the following way:

$$e(f) := 1 \oplus \bigoplus_{n=1}^{\infty} \frac{1}{\sqrt{n!}} f^{\otimes n}$$

which differs from the coherent vector by a normalization factor. The inner products of two exponential vectors e(f) and e(g) is  $\langle e(f), e(g) \rangle = \exp(\langle f, g \rangle)$ . Note that the span of all exponential vectors, denoted  $\mathcal{D}$ , forms a dense subspace of  $\mathcal{F}(\mathcal{H})$ . Let  $f_i$  be the *j*'th component of  $f \in \mathcal{H}$  for j = 1, 2, ..., k. The annihilation operator  $A_j(t)$ , creation operator  $A_i^*(t)$  and number operator  $\Lambda_{ij}(t)$  are defined on the domain  $\mathcal{D}$  by

$$\begin{aligned} A_j(t)e(f) &= \langle \chi_{[0,t]}, f_j \rangle e(f) = \int_0^t f_j(s) ds \ e(f) \\ \langle e(g), A_j^*(t)e(f) \rangle &= \langle g_j, \chi_{[0,t]} \rangle \langle e(g), e(f) \rangle = \int_0^t \overline{g}_j(s) ds \ \exp(\langle f, g \rangle) \\ \langle e(g), \Lambda_{ij}(t)e(f) \rangle &= \langle g_i, \chi_{[0,t]} f_j \rangle \langle e(g), e(f) \rangle = \int_0^t \overline{g}_i(s) f_j(s) ds \ \exp(\langle f, g \rangle). \end{aligned}$$

The operator  $\Lambda_{ii}(t)$  is the usual counting operator for the *i*'th channel. Let us write  $L^2(\mathbb{R}^+)$  as direct sum  $L^2([0,t]) \oplus L^2([t,\infty])$ , then  $\mathcal{F}(L^2(\mathbb{R}_+))$  is unitarily equivalent with  $\mathcal{F}(L^2([0,t]) \otimes \mathcal{F}(L^2[t,\infty))$  through the identification  $e(f) \cong e(f_{t]}) \otimes e(f_{t})$ , with  $f_{t]} = f\chi_{[0,t]}$  and  $f_{[t} = f\chi_{[t,\infty)}$ . We will also use the notation  $f_{[s,t]}$  for  $f\chi_{[s,t]}$  and omit the tensor product signs between exponential vectors. The same procedure can be carried out for all the k channels.

Let  $M_t$  be one of the processes  $A_j(t), A_j^*(t)$  or  $\Lambda_{ij}(t)$ . The following factorisation property [54], [74] makes the definition of stochastic integration against  $M_t$  possible

$$(M_t - M_s)e(f) = e(f_{s})\{(M_t - M_s)e(f_{[s,t]})\}e(f_{[t]}),$$

with  $(M_t - M_s)e(f_{[s,t]}) \in \mathcal{F}(\mathbb{C}^k \otimes L^2([s,t]))$ . We first define the stochastic integral for the so called *simple* operator processes with values in the atom and noise algebra  $\mathcal{B} \otimes \mathcal{W}^{\otimes k}$  where  $\mathcal{B} := M_n$ .

**Definition 3.6.1:** Let  $\{L_s\}_{0 \le s \le t}$  be an adapted (i.e.  $L_s \in \mathcal{B} \otimes \mathcal{W}_{s]}$  for all  $0 \le s \le t$ ) simple process with respect to the partition  $\{s_0 = 0, s_1, \ldots, s_p = t\}$  in the sense that  $L_s = L_{s_j}$  whenever  $s_j \le s < s_{j+1}$ . Then the stochastic integral of L with respect to M on  $\mathbb{C}^n \otimes \mathcal{D}$  is given by [54], [74]:

$$\int_0^t L_s dM_s \ fe(u) := \sum_{j=0}^{p-1} \left( L_{s_j} fe(u_{s_j}] \right) \left( (M_{s_{j+1}} - M_{s_j}) e(u_{[s_j, s_{j+1}]}) \right) e(u_{[s_{j+1}}).$$

By the usual approximation by simple processes we can extend the definition of the stochastic integral to a large class of stochastically integrable processes [54], [74]. We simplify our notation by writing  $dX_t = L_t dM_t$  for  $X_t = X_0 + \int_0^t L_s dM_s$ . Note that the definition of the stochastic integral implies that the increments  $dM_s$  lie in the future, i.e.  $dM_s \in W_{[s]}$ . Another consequence of the definition of the stochastic integral is that its expectation with respect to the vacuum state  $\phi$  is always 0 due to the fact that the increments  $dA_j, dA_j^*, d\Lambda_{ij}$  have zero expectation values in the vacuum. This will often simplify calculations of expectations, our strategy being that of trying to bring these increments to act on the vacuum state thus eliminating a large number of differentials.

The following theorem of Hudson and Parthasarathy extends the Itô rule of classical probability theory.

**Theorem 3.6.2:** (Quantum Itô rule [54], [74]) Let  $M_1$  and  $M_2$  each be one of the processes  $A_j, A_j^*$  or  $\Lambda_{ij}$ . Then  $M_1M_2$  is an adapted process satisfying the relation:

 $d(M_1M_2) = M_1 dM_2 + M_2 dM_1 + dM_1 dM_2,$ 

where  $dM_1 dM_2$  is given by the quantum Itô table:

$dM_1 \backslash dM_2$	$dA_i^*$	$d\Lambda_{ij}$	$dA_i$
$dA_k^*$	0	0	0
$d\Lambda_{kl}$	$\delta_{li} dA_k^*$	$\delta_{li} d\Lambda_{kj}$	0
	$\delta_{ki}dt$	$\delta_{ki} dA_j$	0

**Notation.** The quantum Itô rule will be used for calculating differentials of products of Itô integrals. Let  $\{Z_i\}_{i=1,\dots,p}$  be Itô integrals, then

$$d(Z_1 Z_2 \dots Z_p) = \sum_{\substack{\nu \subset \{1, \dots, p\}\\ \nu \neq \emptyset}} [\nu]$$

where the sum runs over all *non-empty* subsets of  $\{1, \ldots, p\}$  and for any  $\nu = \{i_1, \ldots, i_k\}$ , the term  $[\nu]$  is the contribution to  $d(Z_1Z_2\ldots,Z_p)$  coming from differentiating only the terms with indices in the set  $\{i_1, \ldots, i_k\}$  and preserving the order of the factors in the product. For example the differential  $d(Z_1Z_2Z_3)$  contains terms of the type  $[2] = Z_1(dZ_2)Z_3$ ,  $[13] = (dZ_1)Z_2(dZ_3)$ , and  $[123] = (dZ_1)(dZ_2)(dZ_3)$ .

Let  $V_j$  for j = 1, 2, ..., k, and H be operators in  $\mathcal{B}$  with H is selfadjoint. Let S be a unitary operator on  $\mathbb{C}^n \otimes l^2(\{1, 2, ..., k\})$  with  $S_{ij} = \langle i, Sj \rangle \in \mathcal{B}$  the "matrix elements" in the basis  $\{|i\rangle : i = 1, ..., k\}$  of  $\mathbb{C}^k$ . Then there exists a unique unitary solution for the following quantum stochastic differential equation [54], [74]

$$dU_t = \left\{ V_j dA_j^*(t) + (S_{ij} - \delta_{ij}) d\Lambda_{ij}(t) - V_i^* S_{ij} dA_j(t) - (iH + \frac{1}{2} V_j^* V_j) dt \right\} U_t, \quad (3.19)$$

with initial condition  $U_0 = \mathbf{1}$ , where again repeated indices have been summed. Equation (3.15), providing the cocycle of unitaries perturbing the free evolution of the electromagnetic field is an example of such an equation. The terms  $d\Lambda_{ij}$  in equation (3.19) describe direct scattering between the channels in the electromagnetic field [10]. We have omitted this effect for the sake of simplicity, i.e. we always take  $S_{ij} = \delta_{ij}$ .

We can now check the claim made in Section 3.5 that the dilation diagram 3.16 commutes.

It is easy to see that following the lower part of the diagram defines a semigroup on  $\mathcal{B}$ . We have to show it is generated by L. For all  $X \in \mathcal{B}$  we have

$$d \operatorname{Id} \otimes \phi^k (\hat{T}_t(X \otimes \mathbf{1}^{\otimes k})) = \operatorname{Id} \otimes \phi^k (d U_t^* X \otimes \mathbf{1}^{\otimes k} U_t).$$

Using the Itô rules we obtain

$$d \ U_t^* X \otimes \mathbf{1}^{\otimes k} U_t = (dU_t^*) X \otimes \mathbf{1}^{\otimes k} U_t + U_t^* X \otimes \mathbf{1}^{\otimes k} dU_t + (dU_t^*) X \otimes \mathbf{1}^{\otimes k} dU_t.$$

With the aid of the Itô table we can evaluate these terms. We are only interested in the dt-terms since the expectation with respect to the vacuum kills the other terms. Then we obtain:  $d \operatorname{Id} \otimes \phi^k(U_t^*X \otimes \mathbf{1}^{\otimes k}U_t) = \operatorname{Id} \otimes \phi^k(U_t^*L(X) \otimes \mathbf{1}^{\otimes k}U_t)dt$ , proving the claim.

Now we return to the example of resonance fluorescence. Suppose the laser is off, then we have spontaneous decay of the 2-level atom into the field which is in the vacuum state. For future convenience we already distinguish a *forward* and a *side* channel in the field, the Liouvillian is then given by

$$L(X) = i[H, X] + \sum_{\sigma = f, s} V_{\sigma}^* X V_{\sigma} - \frac{1}{2} \{ V_{\sigma}^* V_{\sigma}, X \},$$

where

$$V = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad V_f = \kappa_f V, \quad V_s = \kappa_s V, \quad |\kappa_f|^2 + |\kappa_s|^2 = 1,$$

with  $|\kappa_f|^2$  and  $|\kappa_s|^2$  the decay rates into the forward and side channel respectively. The dilation of the quantum dynamical system  $(M_2, \{T_t = \exp(tL)\}_{t\geq 0})$ , is now given by the closed system  $(M_2 \otimes \mathcal{W}_f \otimes \mathcal{W}_s, \{\hat{T}_t\}_{t\in\mathbb{R}})$  with unitary cocycle given by

$$dU_t^{sd} = \{V_f dA_f^*(t) - V_f^* dA_f(t) + V_s dA_s^*(t) - V_s^* dA_s(t) - (iH + \frac{1}{2}V^*V)dt\}U_t^{sd}, \quad U_0^{sd} = \mathbf{1},$$

where the superscript sd reminds us of the fact that the laser is off, i.e. we are considering spontaneous decay. We can summarize this in the following dilation diagram

$$\begin{array}{ccc} \mathcal{B} & \xrightarrow{T_t = \exp(tL)} & \mathcal{B} \\ \mathrm{Id} \otimes \mathbf{1} \otimes \mathbf{1} & & \uparrow \mathrm{Id} \otimes \phi \otimes \phi \\ \mathcal{B} \otimes \mathcal{W}_f \otimes \mathcal{W}_s & \xrightarrow{\hat{T}_t^{sd} = \mathrm{Ad}[\hat{U}_t^{sd}]} & \mathcal{B} \otimes \mathcal{W}_f \otimes \mathcal{W}_s \end{array}$$

where  $\hat{U}_t^{sd}$  is given by  $S_t \otimes S_t U_t^{sd}$  for  $t \ge 0$ .

We change this setting by introducing a laser on the forward channel, i.e. the forward channel is now in a coherent state (see 3.6)  $\gamma_h := \langle \psi(h), \cdot \psi(h) \rangle$  for some  $h \in L^2(\mathbb{R}_+)$ .

#### 3.6. QUANTUM STOCHASTIC CALCULUS

This leads to the following dilation diagram

i.e. the evolution on  $\mathcal{B}$  has changed and it is in general *not* a semigroup. Denote by W(h) the unitary Weyl or displacement operator defined on  $\mathcal{D}$  by:  $W(h)\psi(f) = \exp(-2i\mathrm{Im}\langle h, f\rangle)$  $\psi(f+h)$ . Note that  $W(h)\phi = W(h)\psi(0) = \psi(h)$ , so that we can write

$$T_t^h(X) = \mathrm{Id} \otimes \gamma_h \otimes \phi(U_t^{sd^*}X \otimes \mathbf{1} \otimes \mathbf{1}U_t^{sd}) =$$
  
$$\mathrm{Id} \otimes \phi \otimes \phi(W_f(h)^* U_t^{sd^*}X \otimes \mathbf{1} \otimes \mathbf{1}U_t^{sd}W_f(h)) =$$
  
$$\mathrm{Id} \otimes \phi \otimes \phi(W_f(h_{t]})^* U_t^{sd^*}X \otimes \mathbf{1} \otimes \mathbf{1}U_t^{sd}W_f(h_{t]})),$$

where  $h_{t]} := h\chi_{[0,t]}$  and  $W_f(h) := \mathbf{1} \otimes W(h) \otimes \mathbf{1}$ . Defining  $U_t := U_t^{sd} W_f(h_{t]})$ , together with the stochastic differential equation for  $W_f(h_{t]})$  [74]

$$dW_f(h_{t]}) = \{h(t)dA_f^*(t) - \overline{h}(t)dA_f(t) - \frac{1}{2}|h(t)|^2dt\}W_f(h_{t]}), \quad W_f(h_0) = \mathbf{1},$$

and the Itô rules leads to the following quantum stochastic differential equation for  $U_t$ :

$$\begin{aligned} dU_t &= \left\{ (V_f + h(t)) dA_f^*(t) - (V_f^* + \overline{h}(t)) dA_f(t) + V_s dA_s^*(t) - V_s^* dA_s(t) - (iH + \frac{1}{2}(|h(t)|^2 + V^*V + 2h(t)V_f^*)) dt \right\} U_t, \quad U_0 = \mathbf{1}. \end{aligned}$$

Define  $\tilde{V}_f := V_f + h(t)$ ,  $\tilde{V}_s := V_s$  and  $\tilde{H} := H + i\frac{1}{2}(\overline{h}(t)V_f - h(t)V_f^*)$  then this reads

$$dU_{t} = \sum_{\sigma=f,s} \left\{ \tilde{V}_{\sigma} dA_{\sigma}^{*}(t) - \tilde{V}_{\sigma}^{*} dA_{\sigma} - (i\tilde{H} + \frac{1}{2}\tilde{V}_{\sigma}^{*}\tilde{V}_{\sigma})dt \right\} U_{t}, \quad U_{0} = \mathbf{1}.$$
(3.21)

The time dependent generator of the dissipative evolution in the presence of the laser on the forward channel is

$$L(X) = i[\tilde{H}, X] + \sum_{\sigma=f,s} \tilde{V}_{\sigma}^* X \tilde{V}_{\sigma} - \frac{1}{2} \{ \tilde{V}_{\sigma}^* \tilde{V}_{\sigma}, X \}.$$

$$(3.22)$$

Therefore the diagram for resonance fluorescence (3.20) is equivalent to

$$\begin{array}{ccc} \mathcal{B} & \xrightarrow{T_t^n} & \mathcal{B} \\ \mathrm{Id} \otimes \mathbf{1} \otimes \mathbf{1} & & \uparrow \mathrm{Id} \otimes \phi \otimes \phi \\ \mathcal{B} \otimes \mathcal{W}_f \otimes \mathcal{W}_s & \xrightarrow{\hat{T}_t = \mathrm{Ad}[\hat{U}_t]} & \mathcal{B} \otimes W_f \otimes \mathcal{W}_s \end{array}$$

where  $\hat{U}_t$  is given by  $S_t \otimes S_t U_t$  for  $t \ge 0$ . For  $h(t) = -i\frac{\Omega}{2\kappa_f}$ , we find the master equation for resonance fluorescence (3.1). From now on we will no longer suppress the oscillations of the laser, i.e. we take  $h(t) = -i \exp(i\omega t) \frac{\Omega}{2\kappa_f}$ . Then we find

$$L(X) = i[H, X] - i\frac{\Omega}{2}[e^{-i\omega t}V + e^{i\omega t}V^*, X] - \frac{1}{2}\{V^*V, X\} + V^*XV,$$

note that the laser is resonant when  $\omega = \omega_0$ .

## 3.7 Belavkin's stochastic Schrödinger equations

Now we are ready to derive a stochastic differential equation for the process  $\mathcal{E}^t(X)$ . In the next section we will see that this equation leads to the stochastic Schrödinger equations (3.5) and (3.9), that we already encountered in Sections 3.2 and 3.3.

**Definition 3.7.1:** Let X be an element of  $\mathcal{B} := M_n$ . Define the process  $\{M_t^X\}_{t\geq 0}$  in the algebra  $\mathcal{C}_{\infty} \cong L^{\infty}(\Omega, \Sigma, \mathbb{P}_{\rho})$ , generated by the observed process  $\{Y_t\}_{t\geq 0}$  (see Section 3.5) by

$$M_t^X := \mathcal{E}^t(X) - \mathcal{E}^0(X) - \int_0^t \mathcal{E}^r(L(X)) dr,$$

where  $L : \mathcal{B} \to \mathcal{B}$  is the Liouvillian. In the following we suppress the superscript X in  $M_t^X$  to simplify our notation.

Note that from the above definition it is clear that  $M_t$  is an element of  $C_t$  for all  $t \ge 0$ . The following theorem first appeared (in a more general form and with a different proof) in [17] and is at the heart of quantum filtering theory. We prove it using the properties of conditional expectations. For simplicity we have restricted to observing a process in the field  $\mathcal{W}^{\otimes k}$ . The theory can be extended to processes that are in  $\mathcal{B} \otimes \mathcal{W}^{\otimes k}$ , transforming it into a more interesting filtering theory. For the stochastic Schrödinger equations arising in quantum optics our approach is general enough.

**Theorem 3.7.2:** The process  $\{M_t\}_{t\geq 0}$  of definition 3.7.1 is a martingale with respect to the filtration  $\{\Sigma_t\}_{t\geq 0}$  of  $\Omega$  and the measure  $\mathbb{P}_{\rho}$ , i.e. for all  $t\geq s\geq 0$  we have:  $\mathbb{E}_{\rho}^s(M_t)=M_s$ .

*Proof.* From the module property of the conditional expectation it follows that  $\mathbb{E}_{\rho}^{s}(M_{t}) = M_{s}$  for  $t \geq s \geq 0$  is equivalent to  $\mathbb{E}_{\rho}^{s}(M_{t} - M_{s}) = 0$  for  $t \geq s \geq 0$ . This means we have to prove for all  $t \geq s \geq 0$  and  $E \in \Sigma_{s}$ :

$$\int_E \mathbb{E}_{\rho}^s (M_t - M_s)(\omega) \mathbb{P}_{\rho}(d\omega) = 0,$$

## 3.7. BELAVKIN'S STOCHASTIC SCHRÖDINGER EQUATIONS

which, by the tower property, is equivalent to

$$\int_{E} (M_t - M_s)(\omega) \mathbb{P}_{\rho}(d\omega) = 0, \qquad (3.23)$$

i.e.  $\mathbb{E}_{\rho}(\chi_E(M_t - M_s)) = 0$ . Now using Definition 3.7.1 and again the module property of the conditional expectation we find, writing *E* also for the projection corresponding to  $\chi_E$ 

$$\mathbb{E}_{\rho}\big(\chi_{E}(M_{t}-M_{s})\big) = \rho^{\infty}\Big(\mathcal{E}^{t}(X\otimes E) - \mathcal{E}^{s}(X\otimes E) - \int_{s}^{t} \mathcal{E}^{r}\big(L(X)\otimes E\big)dr\Big)$$
$$= \rho^{t}(X\otimes E) - \rho^{s}(X\otimes E) - \int_{s}^{t} \rho^{r}\big(L(X)\otimes E\big)dr.$$

This means we have to prove:  $d\rho^t(X \otimes E) - \rho^t(L(X) \otimes E)dt = 0$ , for all  $t \geq s$ . Note that  $\rho^t(X \otimes E) = \rho^0(U_t^*X \otimes EU_t) = \rho \otimes \phi^{\otimes k}(U_t^*X \otimes EU_t)$ . Therefore  $d\rho^t(X \otimes E) = \rho \otimes \phi^{\otimes k}(d(U_t^*X \otimes EU_t))$ . We will use the notation below Theorem 3.6.2 with  $Z_1 = U_t^*$  and  $Z_2 = X \otimes EU_t$ . Using the quantum Itô table and the fact that only the dt terms survive after taking a vacuum expectation, we find:

$$d\rho^{0}(U_{t}^{*}X \otimes EU_{t}) = \rho^{0}([1]) + \rho^{0}([2]) + \rho^{0}([12]), \text{ where}$$
  

$$\rho^{0}([1]) + \rho^{0}([2]) = \rho^{0}(U_{t}^{*}(i[H, X] \otimes E - \frac{1}{2}\{V_{j}^{*}V_{j}, X\} \otimes E)U_{t})dt$$
  

$$\rho^{0}([12]) = \rho^{0}(U_{t}^{*}(V_{j}^{*}XV_{j}) \otimes EU_{t})dt.$$

This means  $d\rho^t(X \otimes E) = \rho^t(L(X) \otimes E)dt$ , for all  $t \ge s$ , proving the theorem.

Note that in the proof of the above theorem we have used that the projection  $E \in C_s$  commutes with the increments  $dA_j(s)$ ,  $dA_j^*(s)$ , ds and with the processes in front of the increments in equation (3.15), i.e.  $V_j$ ,  $V_j^*$ ,  $V_j^*V_j$  and H. If the theory is extended to a more general filtering theory [17], then these requirements become real restrictions on the process  $\{Y_t\}_{t\geq 0}$ . If they are satisfied the observed process  $\{Y_t\}_{t\geq 0}$  is said to be *self non demolition* [17].

Definition 3.7.1 implies the following stochastic differential equation for the process  $\mathcal{E}^t(X)$ 

$$d\mathcal{E}^t(X) = \mathcal{E}^t(L(X))dt + dM_t, \qquad (3.24)$$

called the *Belavkin equation*. The only thing that remains to be done is linking the increment  $dM_t$  to the increment of the observed process  $dY_t$ .

Let us assume that the observed process  $\{Y_t\}_{t\geq 0}$  satisfies a quantum stochastic differential equation

$$dY_t = \alpha_j(t)dA_j^*(t) + \beta_{ij}(t)d\Lambda_{ij}(t) + \alpha_j^*(t)dA_j(t) + \delta(t)dt,$$

for some adapted stochastically integrable processes  $\alpha_j, \beta_{ij}$ , and  $\delta$ , such that  $\alpha_j(t), \beta_{ij}(t), \delta(t) \in \mathcal{W}_{t|}^{\otimes k}$  for all  $t \geq 0$ , and  $\beta_{ij}^* = \beta_{ji}, \delta = \delta^*$  since  $Y_t$  is selfadjoint. Furthermore, since

the observed process  $\{Y_t\}_{t\geq 0}$  is commutative, we have  $[dY_t, Y_s] = 0$  for all  $s \leq t$ , which leads to

$$\begin{split} & [\alpha_j(t), Y_s] dA_j^*(t) + [\beta_{ij}(t), Y_s] d\Lambda_{ij}(t) + [\alpha_j^*(t), Y_s] dA_j(t) + [\delta(t), Y_s] dt = 0 \quad \Rightarrow \\ & [\alpha_j(t), Y_s] = 0, \quad [\beta_{ij}(t), Y_s] = 0, \quad [\alpha_j^*(t), Y_s] = 0, \quad [\delta(t), Y_s] = 0, \end{split}$$

i.e.  $\alpha_j(t), \beta_{ij}(t), \alpha_j^*(t), \delta(t) \in \mathcal{A}_t$ . This enables us to define a process  $\tilde{Y}_t$  by

$$d\tilde{Y}_{t} = \left(\alpha_{j}(t)dA_{j}^{*}(t) - \mathcal{E}^{t}\left(V_{j}^{*}\alpha_{j}(t)\right)dt\right) + \left(\beta_{ij}(t)d\Lambda_{ij}(t) - \mathcal{E}^{t}\left(V_{i}^{*}\beta_{ij}(t)V_{j}\right)dt\right) + \left(\alpha_{j}^{*}(t)dA_{j}(t) - \mathcal{E}^{t}\left(\alpha_{j}^{*}(t)V_{j}\right)dt\right), \quad \tilde{Y}_{0} = 0,$$
(3.25)

i.e. we have the following splitting of  $Y_t$ :

$$Y_t = Y_0 + \tilde{Y}_t + \int_0^t \left( \mathcal{E}^s \left( V_j^* \alpha_j(s) \right) + \mathcal{E}^s \left( V_i^* \beta_{ij}(s) V_j \right) + \mathcal{E}^s \left( \alpha_j^*(s) V_j \right) + \delta(s) \right) ds, \quad (3.26)$$

which in view of the following theorem is the semi-martingale splitting of  $Y_t$ . The process  $\tilde{Y}_t$  is called the *innovating martingale* of the observed process  $Y_t$ .

**Theorem 3.7.3:** The process  $\{\tilde{Y}_t\}_{t\geq 0}$  is a martingale with respect to the filtration  $\{\Sigma_t\}_{t\geq 0}$  of  $\Omega$  and the measure  $\mathbb{P}_{\rho}$ , i.e. for all  $t\geq s\geq 0$  we have:  $\mathbb{E}_{\rho}^s(\tilde{Y}_t)=\tilde{Y}_s$ .

*Proof.* We need to prove that for all  $t \ge s \ge 0$ :  $\mathbb{E}_{\rho}^{s}(\tilde{Y}_{t} - \tilde{Y}_{s}) = 0$ . This means we have to prove for all  $t \ge s \ge 0$  and  $E \in \Sigma_{s}$ :

$$\int_{E} \mathbb{E}_{\rho}^{s} (\tilde{Y}_{t} - \tilde{Y}_{s})(\omega) \mathbb{P}_{\rho}(d\omega) = 0 \iff \int_{E} (\tilde{Y}_{t} - \tilde{Y}_{s})(\omega) \mathbb{P}_{\rho}(d\omega) = 0 \iff \mathbb{E}_{\rho} \left( Y_{t}E - Y_{s}E - \int_{s}^{t} \left( \mathcal{E}^{r} \left( V_{j}^{*} \alpha_{j}(r) \right) E + \mathcal{E}^{r} \left( V_{i}^{*} \beta_{ij}(r) V_{j} \right) E + \mathcal{E}^{r} \left( \alpha_{j}^{*}(r) V_{j} \right) E + \delta(r) E \right) dr \right) = 0 \iff \rho^{t} (Y_{t}E) - \rho^{s} (Y_{s}E) = \int_{s}^{t} \rho^{r} \left( \mathcal{E}^{r} \left( V_{j}^{*} \alpha_{j}(r) \right) E + \mathcal{E}^{r} \left( V_{i}^{*} \beta_{ij}(r) V_{j} \right) E + \mathcal{E}^{r} \left( \alpha_{j}^{*}(r) V_{j} \right) E + \delta(r) E \right) dr.$$

For t = s this is okay, so it remains to be shown that for all  $t \ge s \ge 0$  and  $E \in \Sigma_s$ :

$$d\rho^{t}(Y_{t}E) = \rho^{t} \Big( \mathcal{E}^{t} \big( V_{j}^{*} \alpha_{j}(t) \big) E + \mathcal{E}^{t} \big( V_{i}^{*} \beta_{ij}(t) V_{j} \big) E + \mathcal{E}^{t} \big( \alpha_{j}^{*}(t) V_{j} \big) E + \delta(t) E \Big) dt \iff d\rho^{0} (U_{t}^{*} Y_{t}EU_{t}) = \rho^{t} \Big( \mathcal{E}^{t} \big( V_{j}^{*} \alpha_{j}(t) \big) E + \mathcal{E}^{t} \big( V_{i}^{*} \beta_{ij}(t) V_{j} \big) E + \mathcal{E}^{t} \big( \alpha_{j}^{*}(t) V_{j} \big) E + \delta(t) E \Big) dt.$$

We define:  $Z_1(t) := U_t^*$ ,  $Z_2(t) := Y_t E$  and  $Z_3(t) := U_t$  then we find, using the notation below Theorem 3.6.2:  $d\rho^0(U_t^*Y_tEU_t) = \rho^0([1] + [2] + [3] + [12] + [13] + [23] + [123])$ . Remember  $\rho^0 = \rho \otimes \phi^{\otimes k}$ , i.e. we are only interested in the dt terms, since the vacuum kills all other terms. The terms [1], [3] and [13] together make up the usual Lindblad term and since  $L(\mathbf{1}) = 0$  we do not have to consider them.

Furthermore, term [2] contributes  $U_t^*\delta(t)EU_tdt$ , term [12] contributes  $U_t^*V_j^*\alpha_j(t)E \ U_tdt$ , term [23] contributes  $U_t^*\alpha_j^*(t)V_jEU_tdt$  and term [123] contributes  $U_t^*V_i^*\beta_{ij}(t)V_j \ U_tdt$ , therefore we get

$$d\rho^{0}(U_{t}^{*}Y_{t}EU_{t}) = \\\rho^{0}(U_{t}^{*}\alpha_{j}^{*}(t)V_{j}EU_{t} + U_{t}^{*}V_{i}^{*}\beta_{ij}(t)V_{j}U_{t} + U_{t}^{*}V_{j}^{*}\alpha_{j}(t)EU_{t} + U_{t}^{*}\delta(t)EU_{t})dt = \\\rho^{t}(\alpha_{j}^{*}(t)V_{j}E + V_{i}^{*}\beta_{ij}(t)V_{j} + V_{j}^{*}\alpha_{j}(t)E + \delta(t)E)dt = \\\rho^{t}(\mathcal{E}^{t}(V_{j}^{*}\alpha_{j}(t))E + \mathcal{E}^{t}(V_{i}^{*}\beta_{ij}(t)V_{j})E + \mathcal{E}^{t}(\alpha_{j}^{*}(t)V_{j})E + \delta(t)E)dt,$$

proving the theorem.

**Remark.** In the probability literature an adapted process which can be written as the sum of a martingale and a finite variation process is called a semimartingale [77]. The Theorems 3.7.2 and 3.7.3 show that  $M_t$  and  $Y_t$  are semimartingales.

We now represent the martingale  $M_t$  from Definition 3.7.1 as an integral over the innovating martingale (cf. [57]) by

$$dM_t = \eta_t d\dot{Y}_t \tag{3.27}$$

for some stochastically integrable process  $\eta_t$ , which together with equation (3.26) provides the link between  $dM_t$  and  $dY_t$ . We are left with the problem of determining  $\eta_t$ , which we will carry out in the next section for the examples of Section 3.2 and 3.3. Here we just give the recipe for finding  $\eta_t$ .

**Recipe.** Define for all integrable adapted processes  $b_t$  and  $c_t$  a process  $B_t$  in  $\mathcal{C}_{\infty}$  by

$$dB_t = b_t dY_t + c_t dt. aga{3.28}$$

These processes form a dense subalgebra of  $\mathcal{C}_{\infty}$ . Now determine  $\eta_t$  from the fact that  $\mathcal{E}^t$  leaves  $\rho^t$  invariant [17], i.e. for all  $B_t$ 

$$\rho^t \big( \mathcal{E}^t (B_t X) \big) = \rho^t (B_t X).$$

From this it follows that for all  $B_t$ 

$$d\rho^{0} (U_{t}^{*} B_{t} (\mathcal{E}^{t}(X) - X) U_{t}) = 0.$$
(3.29)

We evaluate the differential  $d(U_t^*B_t(\mathcal{E}^t(X) - X)U_t)$  using the quantum Itô rules. Since  $\rho^0 = \rho \otimes \phi^{\otimes k}$  we can restrict to the dt terms, since the others die on the vacuum. We will use the notation below Theorem 3.6.2 with  $Z_1(t) = U_t^*$ ,  $Z_2(t) = B_t, Z_3(t) = \mathcal{E}^t(X) - X$  and  $Z_4(t) = U_t$ . The following lemma simplifies the calculation considerably.

**Lemma 3.7.4:** The sum of all terms in which  $Z_2$  is not differentiated has zero expectation:  $\rho^0([1] + [3] + [4] + [13] + [14] + [34] + [134]) = 0.$ 

Proof. The dt terms of [3] are  $U_t^* B_t \mathcal{E}^t (L(X)) U_t dt$  and  $-U_t^* B_t \eta_t (\mathcal{E}^t (V_j^* \alpha_j) + \mathcal{E}^t (V_i^* \beta_{ij})) + \mathcal{E}^t (\alpha_j^* V_j) U_t dt$ . Using the fact that  $\mathcal{E}^t$  leaves  $\rho^t$  invariant we see that the term  $U_t^* B_t \mathcal{E}^t (L(X)) U_t dt$  cancels against the dt terms of [1], [4] and [14], which make up the Lindblad generator L with a minus sign. The other term of [3] is cancelled in expectation against the dt terms of [13], [34] and [134], since

$$\rho^{0}([13]) = \rho^{t}(B_{t}\eta_{t}V_{j}^{*}\alpha_{j})dt = \rho^{t}\left(\mathcal{E}^{t}(B_{t}\eta_{t}V_{j}^{*}\alpha_{j})\right)dt = \rho^{t}\left(B_{t}\eta_{t}\mathcal{E}^{t}(V_{j}^{*}\alpha_{j})\right)dt$$
$$\rho^{0}([34]) = \rho^{t}(B_{t}\eta_{t}\alpha_{j}^{*}V_{j})dt = \rho^{t}\left(\mathcal{E}^{t}(B_{t}\eta_{t}\alpha_{j}^{*}V_{j})\right)dt = \rho^{t}\left(B_{t}\eta_{t}\mathcal{E}^{t}(\alpha_{j}^{*}V_{j})\right)dt$$
$$\rho^{0}([134]) = \rho^{t}(B_{t}\eta_{t}V_{i}^{*}\beta_{ij}V_{j})dt = \rho^{t}\left(\mathcal{E}^{t}(B_{t}\eta_{t}V_{i}^{*}\beta_{ij}V_{j})\right)dt = \rho^{t}\left(B_{t}\eta_{t}\mathcal{E}^{t}(V_{i}^{*}\beta_{ij}V_{j})\right)dt.$$

Using equation (3.25), the fact that  $\mathcal{E}^t$  leaves  $\rho^t$  invariant and the module property, we find that the term [2] has expectation zero as well

$$\rho^{0}([2]) = \rho^{t} \left( b_{t} d\tilde{Y}_{t}(\mathcal{E}^{t}(X) - X) \right) =$$
  
-  $\rho^{t} \left( b_{t} \mathcal{E}^{t}(V_{j}^{*} \alpha_{j}(t) + \alpha_{j}^{*}(t)V_{j} + V_{i}^{*} \beta_{ij}V_{j})(\mathcal{E}^{t}(X) - X) \right) dt =$   
-  $\rho^{t} \left( b_{t} \mathcal{E}^{t}(V_{j}^{*} \alpha_{j}(t) + \alpha_{j}^{*}(t)V_{j} + V_{i}^{*} \beta_{ij}V_{j})\mathcal{E}^{t}(\mathcal{E}^{t}(X) - X) \right) dt = 0.$ 

Thus, only the terms containing no  $B_t$  nor  $c_t$  can contribute non-trivially. This leads to an equation allowing us to obtain an expression for  $\eta_t$  by solving

$$\rho^{0}([12] + [23] + [24] + [123] + [124] + [234] + [1234]) = 0.$$
(3.30)

Although this can be carried out in full generality, we will provide the solution only for our main examples, the photon counting and homodyne detection experiments for a resonance fluorescence setup, in the next section.

## 3.8 Examples

We now return to the example considered in Section 3.2. We were considering a 2-level atom in interaction with the electromagnetic field. The interaction was given by a cocycle  $U_t$  satisfying equation (3.21). The observed process is the number operator in the side channel, i.e.  $Y_t = \Lambda_{ss}(t)$ . Therefore  $d\tilde{Y}_t = d\Lambda_{ss}(t) - \mathcal{E}^t(V_s^*V_s)dt$ . Recall now the notation  $Z_1(t) = U_t^*$ ,  $Z_2(t) = B_t, Z_3(t) = \mathcal{E}^t(X) - X$  and  $Z_4(t) = U_t$ , their differentials are given by

$$dU_t^* = U_t^* \sum_{\sigma=f,s} \left\{ \tilde{V}_{\sigma}^* dA_{\sigma}(t) - \tilde{V}_{\sigma} dA_{\sigma}^*(t) - (-i\tilde{H} + \frac{1}{2}\tilde{V}_{\sigma}^*\tilde{V}_{\sigma})dt \right\}$$
$$dB_t = b_t d\Lambda_{ss}(t) + \left(c_t - b_t \mathcal{E}^t(V_s^*V_s)\right) dt$$
$$d(\mathcal{E}^t(X) - X) = \eta_t d\Lambda_{ss}(t) + \left(\mathcal{E}^t(L(X)) - \eta_t \mathcal{E}^t(V_s^*V_s)\right) dt$$
$$dU_t = \sum_{\sigma=f,s} \left\{ \tilde{V}_{\sigma} dA_{\sigma}^*(t) - \tilde{V}_{\sigma}^* dA_{\sigma}(t) - (i\tilde{H} + \frac{1}{2}\tilde{V}_{\sigma}^*\tilde{V}_{\sigma})dt \right\} U_t.$$

Following the recipe of the previous section we now only have to determine the dt terms of [12], [23], [24], [124], [123], [124] and [1234]. All of these terms are zero in expectation with respect to  $\rho^0$ , except for [124] and [1234]

$$\rho^0([124]) = \rho^0(U_t^*b_t V_s^*(\mathcal{E}^t(X) - X)V_s U_t)dt$$
$$\rho^0([1234]) = \rho^0(U_t^*b_t \eta_t V_s^* V_s U_t)dt.$$

For all  $b_t$  the sum of these terms has to be 0 in expectation, i.e.

$$\begin{aligned} \forall b_t : \ \rho^t \bigg( b_t \Big( V_s^* \big( \mathcal{E}^t(X) - X \big) V_s + \eta_t V_s^* V_s \big) \bigg) dt &= 0 \iff \\ \forall b_t : \ \rho^t \bigg( \mathcal{E}^t \bigg( b_t \Big( V_s^* \big( \mathcal{E}^t(X) - X \big) V_s + \eta_t V_s^* V_s \big) \bigg) \bigg) dt &= 0 \iff \\ \forall b_t : \ \rho^t \bigg( b_t \Big( \mathcal{E}^t(X) \mathcal{E}^t(V_s^* V_s) - \mathcal{E}^t(V_s^* X V_s) + \eta_t \mathcal{E}^t(V_s^* V_s) \big) \bigg) dt &= 0 \iff \\ \eta_t &= \frac{\mathcal{E}^t(V_s^* X V_s)}{\mathcal{E}^t(V_s^* V_s)} - \mathcal{E}^t(X). \end{aligned}$$

Substituting the expressions for  $\eta_t$  and  $\tilde{Y}_t$  into equation (3.24) we obtain the Belavkin equation for photon counting in the side channel

$$d\mathcal{E}^{t}(X) = \mathcal{E}^{t}(L(X))dt + \left(\frac{\mathcal{E}^{t}(V_{s}^{*}XV_{s})}{\mathcal{E}^{t}(V_{s}^{*}V_{s})} - \mathcal{E}^{t}(X)\right)\left(d\Lambda_{ss}(t) - \mathcal{E}^{t}(V_{s}^{*}V_{s})dt\right).$$
(3.31)

Now recall that  $\mathcal{E}^t(X) = \rho^t_{\bullet}(X_{\bullet})$ , i.e. it is the function  $\Omega_t \to \mathbb{C}$ :  $\omega \mapsto \rho^t_{\omega}(X_{\omega})$ . For all  $X \in \mathcal{B} = M_2$ , the  $M_2$  valued function  $X_{\bullet}$  is the constant function  $\omega \mapsto X$ . Therefore for all X in  $\mathcal{B}$ , the Belavkin equation (3.31) is equivalent to

$$d\rho_{\bullet}^{t}(X) = \rho_{\bullet}^{t} \left( L(X) \right) dt + \left( \frac{\rho_{\bullet}^{t}(V_{s}^{*}XV_{s})}{\rho_{\bullet}^{t}(V_{s}^{*}V_{s})} - \rho_{\bullet}^{t}(X) \right) \left( d\Lambda_{ss}(t) - \rho_{\bullet}^{t}(V_{s}^{*}V_{s}) dt \right),$$

which is equivalent to the Belavkin equation of Section 3.2, equation (3.5). In simulating the above equation we can take for  $Y_t = \Lambda_{ss}(t)$  the unique jump process with independent jumps and rate  $\rho_{\bullet}^t(V_s^*V_s)$ , since  $\Lambda_{ss}(t) - \int_0^t \rho_{\bullet}^r(V_s^*V_s) dr$  has to be a martingale.

Let us now turn to the homodyne detection scheme which we already discussed in Section 3.3. The observed process is now  $Y_t = X_{\phi}(t) = A_s^*(f_t) + A_s(f_t)$  (see Section 3.3 for the definition of  $f_t$ ). This means the innovating martingale  $\tilde{Y}_t$  satisfies  $d\tilde{Y}_t = e^{i\phi_t} dA_s^*(t) + e^{-i\phi_t} dA_s(t) - \mathcal{E}^t(e^{i\phi_t}V_s^* + e^{-i\phi_t}V_s)dt$ , where  $\phi_t = \phi_0 + \omega_{lo}t$  with  $\omega_{lo}$  the frequency of the local oscillator. Therefore we find different differentials for  $B_t$  and  $\mathcal{E}^t(X) - X$  than we had in the photon counting case

$$dB_{t} = b_{t} \left( e^{i\phi_{t}} dA_{s}^{*}(t) + e^{-i\phi_{t}} dA_{s}(t) \right) + \left( c_{t} - b_{t} \mathcal{E}^{t} (e^{i\phi_{t}} V_{s}^{*} + e^{-i\phi_{t}} V_{s}) \right) dt$$
  
$$d(\mathcal{E}^{t}(X) - X) = \eta_{t} \left( e^{i\phi_{t}} dA_{s}^{*}(t) + e^{-i\phi_{t}} dA_{s}(t) \right) + \left( \mathcal{E}^{t} \left( L(X) \right) - \eta_{t} \mathcal{E}^{t} (e^{i\phi_{t}} V_{s}^{*} + e^{-i\phi_{t}} V_{s}) \right) dt$$

Following the recipe of the previous section we now only have to determine the dt terms of [12], [23], [24], [124], [123], [124] and [1234]. All of these terms are zero in expectation with respect to  $\rho^0$ , except for [12], [23] and [24]

$$\rho^{0}([12]) = \rho^{0} \left( U_{t}^{*} e^{i\phi_{t}} V_{s}^{*} b_{t} \left( \mathcal{E}^{t}(X) - X \right) U_{t} \right) dt$$
  

$$\rho^{0}([23]) = \rho^{0} \left( U_{t}^{*} b_{t} \eta_{t} U_{t} \right) dt$$
  

$$\rho^{0}([24]) = \rho^{0} \left( U_{t}^{*} b_{t} \left( \mathcal{E}^{t}(X) - X \right) e^{-i\phi_{t}} V_{s} U_{t} \right) dt.$$

For all  $b_t$  the sum of these terms has to be 0 in expectation, i.e.

$$\begin{aligned} \forall b_t : \ \rho^t \Biggl( b_t \Bigl( e^{i\phi_t} V_s^* \bigl( \mathcal{E}^t(X) - X \bigr) + \bigl( \mathcal{E}^t(X) - X \bigr) e^{-i\phi_t} V_s + \eta_t \Bigr) \Biggr) dt &= 0 \iff \\ \forall b_t : \ \rho^t \Biggl( \mathcal{E}^t \Biggl( b_t \Bigl( e^{i\phi_t} V_s^* \bigl( \mathcal{E}^t(X) - X \bigr) + \bigl( \mathcal{E}^t(X) - X \bigr) e^{-i\phi_t} V_s + \eta_t \Bigr) \Biggr) \Biggr) dt &= 0 \iff \\ \forall b_t : \ \rho^t \Bigl( b_t \Bigl( - \mathcal{E}^t \bigl( e^{i\phi_t} V_s^* X + e^{-i\phi_t} X V_s \bigr) + \\ \mathcal{E}^t \bigl( e^{i\phi_t} V_s^* + e^{-i\phi_t} V_s \bigr) \mathcal{E}^t(X) + \eta_t \Bigr) \Bigr) dt &= 0 \iff \\ \eta_t &= \mathcal{E}^t \bigl( e^{i\phi_t} V_s^* X + e^{-i\phi_t} X V_s \bigr) - \mathcal{E}^t \bigl( e^{i\phi_t} V_s^* + e^{-i\phi_t} V_s \bigr) \mathcal{E}^t(X). \end{aligned}$$

Substituting the expressions for  $\eta_t$  and  $\tilde{Y}_t$  into equation (3.24) we obtain the Belavkin equation for the homodyne detection scheme

$$d\mathcal{E}^{t}(X) = \mathcal{E}^{t}(L(X))dt + \left(\mathcal{E}^{t}(e^{i\phi_{t}}V_{s}^{*}X + e^{-i\phi_{t}}XV_{s}) - \mathcal{E}^{t}(e^{i\phi_{t}}V_{s}^{*} + e^{-i\phi_{t}}V_{s})\mathcal{E}^{t}(X)\right) \times \left(e^{i\phi_{t}}dA_{s}^{*}(t) + e^{-i\phi_{t}}dA_{s}(t) - \mathcal{E}^{t}(e^{i\phi_{t}}V_{s}^{*} + e^{-i\phi_{t}}V_{s})dt\right).$$

$$(3.32)$$

Now recall that  $\mathcal{E}^t(X) = \rho^t_{\bullet}(X_{\bullet})$ , i.e. it is the function  $\Omega_t \to \mathbb{C}$ :  $\omega \mapsto \rho^t_{\omega}(X_{\omega})$ . For all  $X \in \mathcal{B} = M_2$ , the  $M_2$  valued function  $X_{\bullet}$  is the constant function  $\omega \mapsto X$ . Therefore for all X in  $\mathcal{B}$ , the Belavkin equation (3.32) is equivalent to

$$d\rho_{\bullet}^{t}(X) = \rho_{\bullet}^{t}(L(X))dt + \left(\rho_{\bullet}^{t}(e^{i\phi_{t}}V_{s}^{*}X + e^{-i\phi_{t}}XV_{s}) - \rho_{\bullet}^{t}(e^{i\phi_{t}}V_{s}^{*} + e^{-i\phi_{t}}V_{s})\rho_{\bullet}^{t}(X)\right) \times \left(e^{i\phi_{t}}dA_{s}^{*}(t) + e^{-i\phi_{t}}dA_{s}(t) - \rho_{\bullet}^{t}(e^{i\phi_{t}}V_{s}^{*} + e^{-i\phi_{t}}V_{s})dt\right),$$

which is equivalent to the Belavkin equation of Section 3.3, equation (3.9). Since  $A_s^*(f_t) + A_s(f_t) - \int_0^t \rho_{\bullet}^r (e^{i\phi_r} V_s^* + e^{-i\phi_r} V_s) dr$  is a martingale with variance t on the space of the Wiener process, it must be the Wiener process itself.

# Squeezing enhanced control

Luc Bouten

Mathematisch Instituut, Katholieke Universiteit Nijmegen Toernooiveld 1, 6526 ED Nijmegen, The Netherlands

### $\mathbf{Abstract}^1$

We study an open system in contact with its environment, the electromagnetic field. The information gained by measuring a quadrature of the field is used to send control pulses to the system. Goal is to fix the unknown state of the system in time. We show that in the special case of an essentially commutative interaction this goal can be achieved. In dealing with spontaneous decay we approximate the essentially commutative situation by bringing the field in a squeezed state. We show that when squeezing goes to infinity, the state can again be kept fixed.

# 4.1 Introduction

The last decade there have been rapid developments in quantum information theory, initiated mainly by some fundamental papers [79], [39] showing the increased possibilities when quantum features are exploited in computations. However, implementation of the

<sup>&</sup>lt;sup>1</sup>This chapter is based on [22].

proposed algorithms on real physical qubits still poses a great challenge. One of the problems is the interaction with the environment, i.e. the electromagnetic field, and the decoherence that goes along with it. Dealing with this problem motivates the development of theory and methods for coherently manipulating, or controlling, quantum systems.

Decoherence is a result of ignoring information lost from an open quantum system to its environment via their interaction. However, the lost information can be retrieved, at least partially, by observing the environment, i.e. by performing measurements on it. The decoherence can be combatted by using the retrieved information in a scheme for controlling the quantum system, see also [51].

Since the electromagnetic field and the open system are in interaction, information on the system itself is gained when measuring some observables of the field. Hence conditioning on the obtained measurement results provides a back-action of the measurement in the field on the open system. One of the pioneers in this area is Belavkin who extended many ideas in classical filtering theory, cf. [83], to the quantum regime [11], [17]. Quantum filtering theory [14], [17] explains how the state, conditioned on the result of a continuous time measurement in the environment, evolves in time. Note that since the results of the continuous time measurement are random, the conditioned state is also a random state. Quantum filtering theory provides a stochastic differential equation, the *Belavkin equation*, for the state evolution in which the measurement process is one of its driving terms [14], [17].

Another approach to the back-action due to conditioning, is via quantum trajectory theory as developed in quantum optics in the late 1980's and early 1990's [27], but already envisioned by Davies [82], [33] in the 1970's. In this approach photon counting measurements are analysed to obtain a continuous time evolution of the open system interrupted by jumps the moments at which photons are detected. Differentiation of the trajectory evolution leads to a *stochastic Schrödinger equation* [28], which is a stochastic differential equation for the evolution of the state conditioned on the outcomes of the counting experiment. A diffusive limit of photon counting in which the jumps in the state space decrease in size but become increasingly frequent, makes it possible to incorporate homodyne and heterodyne detection schemes into quantum trajectory theory [9], [27], [92]. The stochastic Schrödinger equations encountered in quantum optics are equivalent to the Belavkin equations from quantum filtering theory [17], [23].

The result of the continuous time measurement in the field can be used to exert control over the system. The solution to the quantum filtering problem [11], [14] makes it possible to directly carry over many ideas in classical control theory [83], [65], [66] to the quantum regime, [12], [13], [14], [18], [36], [86]. Coming from the quantum trajectory approach, other pionering work in quantum control was done by Wiseman and Milburn in the first half of the 1990's, see [91], [90], [93]. Two different objectives in control problems can be distinguished, one where the state is controlled in order to let it follow a certain path in

time [18], [36], and one where the semigroup describing the dissipative evolution of the open system, i.e. the channel itself, is being controlled [71], [51], [3], [4].

In this paper a problem of the second type is considered. The question addressed here is how to keep an unknown state of an open system fixed in time, i.e. how to keep its dynamical semigroup as close to identity as possible. In this article we will not be concerned with optimality results. The main issue is to find or engineer situations where the control is perfect, in which case the control scheme is said to *restore quantum information* [51]. Furthermore, we will not be concerned here with encoding our system into the code space of a larger system and then protecting just this code space [5], [4].

The control scheme consists of two parts. The first part is an evolution over a period of  $\tau$  time units in which a quadrature of the field is observed. This evolution is governed by the Belavkin equation corresponding to this measurement. In the second part the result of the measurement is used to construct a laser pulse designed, if at all possible, to take the system through a Rabi cycle that corrects the evolution of the past  $\tau$  time units. This scheme is studied in the limit for very small  $\tau$ , i.e. the control pulses are sent at very high frequency.

In general the above control scheme will not be able to restore quantum information. Since the interaction of the field and the system is studied in the weak coupling limit, the field acts as two classical noises. However these two noises, represented by two different quadratures of the field, do not commute with each other. Therefore only one of these noises can be observed and its disturbing effect on the system corrected. An idealised interaction of system and field in which there is only one instead of two classical noises present is called *essentially commutative* [63]. In the essentially commutative case it will turn out that the above control scheme restores quantum information.

For the more realistic situation where both noises are present our strategy will be to manipulate the state of the field in order to approximate the essentially commutative case. This is done by putting the field in a squeezed state, i.e. one quadrature's variance increases while the other quadrature's variance decreases, [42], [43], [58]. The idea is to measure the noise with the large variance and correct its disturbing effect on the system. It will turn out that when squeezing goes to infinity the control scheme described above will restore quantum information.

This paper is organised as follows. Section 4.2 describes the dissipative evolution of the open system within the Markov approximation. The joint evolution of system and field is given by unitaries satisfying a quantum stochastic differential equation in the sense of [54]. In the next section a brief exposition of quantum stochastic calculus [54] is given. This enables us to make sense of the quantum stochastic differential equation providing the unitaries of section 4.2. Sections 4.2 and 4.3 describe dilation theory and quantum stochastic calculus in a nutshell. Section 4.4 is a brief exposition of quantum filtering

theory. It contains a derivation of the Belavkin equation for field quadrature measurement.

Sections 4.5 and 4.6 deal with controlling the state of an open system in the essentially commutative case and the more realistic situation of spontaneous decay of a two-level system, respectively. Here we show that for the essentially commutative case it is possible to restore quantum information. For spontaneous decay, however, problems are encountered motivating the investigation in the remainder of the paper.

Section 4.7 shows how to describe the interaction of system and field when the field is in a squeezed state. To do this we have to do quantum stochastic calculus in the GNSrepresentation space of the squeezed state. In the last section the Belavkin equation for measuring a quadrature of a squeezed field is given and a control scheme based on this measurement is presented. It turns out that when squeezing goes to infinity, the scheme restores quantum information.

## 4.2 The dilation

Let  $\mathcal{B} := M_n$  stand for the algebra of observables of an *n*-dimensional quantum system. On this algebra  $\{T_t\}_{t\geq 0}$  is a semigroup of completely positive identity preserving operators. It represents the irreversible time evolution of the system in the Heisenberg picture. Lindblad's theorem [67] asserts that  $T_t = \exp(tL)$  where the generator L is given by

$$L(X) = i[H, X] + \sum_{j=1}^{k} V_j^* X V_j - \frac{1}{2} \{ V_j^* V_j, X \}, \quad X \in \mathcal{B},$$

with H and the  $V'_j s$  fixed elements of  $\mathcal{B}$ , H being selfadjoint. The notation  $\{X, Y\}$  stands for the anticommutator XY + YX. For simplicity, we take k = 1 and H = 0, i.e.

$$L(X) = V^* X V - \frac{1}{2} \{ V^* V, X \}.$$
(4.1)

This paper deals mainly with two special cases of the above situation. In the first special case we have either  $V = V^*$  or  $V = -V^*$ . This case is called *essentially commutative* [63], see section 4.5. In the second special case we have

$$V = \begin{pmatrix} 0 & 0\\ 1 & 0 \end{pmatrix}. \tag{4.2}$$

Then the semigroup  $T_t$  describes spontaneous decay to the ground state of a two-level system, see sections 4.6 and 4.8.

The system  $\mathcal{B}$  and its environment, the electromagnetic field, evolve reversibly in time. The irreversible evolution  $T_t$  of  $\mathcal{B}$  is the result after tracing out the field. Up to section 4.7 the electromagnetic field to which the system  $\mathcal{B}$  is coupled, will be taken in the vacuum state or a coherent state. Then, see section 4.7 for more details, a decay channel in the field can be modelled by the *bosonic* or *symmetric Fock space* over the Hilbert space  $L^2(\mathbb{R})$  of square integrable wave functions on the real line, i.e.

$$\mathcal{F} := \mathbb{C} \oplus \bigoplus_{n=1}^{\infty} L^2(\mathbb{R})^{\otimes_s n}$$

The algebra generated by the field observables on  $\mathcal{F}$  contains all bounded operators and it is denoted by  $\mathcal{W}$ .

For future convenience we already distinguish two decay channels in the field, i.e. we rewrite L as

$$L(X) = V_f^* X V_f - \frac{1}{2} \{ V_f^* V_f, X \} + V_s^* X V_s - \frac{1}{2} \{ V_s^* V_s, X \}, \quad X \in \mathcal{B},$$
(4.3)

where  $V_f = \kappa_f V$ ,  $V_s = \kappa_s V$  and  $\kappa_f, \kappa_s \in \mathbb{R}$  such that  $|\kappa_f|^2 + |\kappa_s|^2 = 1$ . The subscripts f and s stand for *forward* and *side channel*, respectively. On the forward channel in the field we will put a laser with which we want to control the system, while in the side channel of the field we are going to perform a measurement. The decay rates into the forward and side channel are given by  $|\kappa_f|^2$  and  $|\kappa_s|^2$ , respectively. Since the field is modelled by these two decay channels, we need two copies of the algebra  $\mathcal{W}$ , denoted  $\mathcal{W}^f \otimes \mathcal{W}^s$ .

The free evolution of a channel in the field is given by the unitary group  $S_t$ , the second quantization of the left shift s(t) on  $L^2(\mathbb{R})$ , i.e.  $s(t) : f \mapsto f(\cdot + t)$ . In the Heisenberg picture the evolution on  $\mathcal{W}^f \otimes \mathcal{W}^s$  is

$$W \mapsto (S_t \otimes S_t)^* W(S_t \otimes S_t) := \operatorname{Ad}[S_t \otimes S_t](W), \quad W \in \mathcal{W}^f \otimes \mathcal{W}^s.$$

The system  $\mathcal{B}$  and field together form a closed system, thus their joint evolution is given by a one-parameter group  $\{\hat{T}_t\}_{t\in\mathbb{R}}$  of \*-automorphisms on  $\mathcal{B}\otimes\mathcal{W}^f\otimes\mathcal{W}^s$ 

$$X \mapsto \hat{U}_t^* X \hat{U}_t := \operatorname{Ad}[\hat{U}_t](X), \quad X \in \mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s.$$

The group  $\hat{U}_t$  is a perturbation of the free evolution without interaction. We describe this perturbation by the family of unitaries  $U_t := (S_{-t} \otimes S_{-t})\hat{U}_t$  for all  $t \in \mathbb{R}$  satisfying the *cocycle* identity

$$U_{t+s} = (S_{-s} \otimes S_{-s})U_t(S_s \otimes S_s)U_s, \text{ for all } t, s \in \mathbb{R}.$$

The direct connection between the reduced evolution of  $\mathcal{B}$  given by (4.3) and the cocycle  $U_t$  is one of the important results of quantum stochastic calculus [54] which is the object of the next section. For the moment we only mention that in the weak coupling limit [2],  $U_t$  is the solution of the stochastic differential equation [54], [74], [72]

$$dU_t = \{V_f dA_f^*(t) - V_f^* dA_f(t) + V_s dA_s^*(t) - V_s^* dA_s(t) - \frac{1}{2} V^* V dt\} U_t, \quad U_0 = \mathbf{1}.$$
 (4.4)

We will see in the next section that if  $U_t$  satisfies (4.4) the following *dilation diagram* [59], [60] commutes:

i.e. for all  $X \in \mathcal{B}$ :  $T_t(X) = (\mathrm{Id} \otimes \phi \otimes \phi) (\hat{T}_t(X \otimes \mathbf{1} \otimes \mathbf{1}))$ , where  $\phi$  is the vacuum state on  $\mathcal{W}$ , and  $\mathbf{1}$  is the identity operator in  $\mathcal{W}$ . Any dilation of the semigroup  $T_t$  with Bose fields is unitarily equivalent with the above one under certain minimality requirements.

The dilation diagram can also be read in the Schrödinger picture if we reverse the arrows: start with a state  $\rho$  of the system  $\mathcal{B}$  in the upper right hand corner, then this state undergoes the following sequence of maps

$$\rho \mapsto \rho \otimes \phi \otimes \phi \mapsto \rho \otimes \phi \otimes \phi \circ \hat{T}_t = \hat{T}_{t*}(\rho \otimes \phi \otimes \phi) \mapsto \operatorname{Tr}_{\mathcal{F}^f \otimes \mathcal{F}^s}(\hat{T}_{t*}(\rho \otimes \phi \otimes \phi)).$$

This means that at t = 0, the atom in the state  $\rho$  is coupled to the electromagnetic field in the vacuum state, after t seconds of unitary evolution the partial trace over the field is taken.

## 4.3 Quantum stochastic calculus

Here, we briefly discuss the quantum stochastic calculus developed by Hudson and Parthasarathy [54]. For a detailed treatment of the subject we refer to [74] and [72]. The exposition here is a bit broader than strictly necessary for the construction of the cocycle of the previous section. However, the general description [74] presented here is needed in section 4.7.

Let  $\mathcal{H}$  be a Hilbert space. We define the bosonic or symmetric Fock space over  $\mathcal{H}$  by

$$\mathcal{F}(\mathcal{H}) := \mathbb{C} \oplus \bigoplus_{k=1}^{\infty} \mathcal{H}^{\otimes_s k}.$$

In the previous section we had  $\mathcal{H} = L^2(\mathbb{R})$ . For every  $f \in \mathcal{H}$  we define the *exponential* vector  $e(f) \in \mathcal{F}(\mathcal{H})$  in the following way

$$e(f) := 1 \oplus \bigoplus_{k=1}^{\infty} \frac{1}{\sqrt{k!}} f^{\otimes k}.$$

The inner product of two exponential vectors e(f) and e(g) is  $\langle e(f), e(g) \rangle = \exp(\langle f, g \rangle)$ . We denote the vacuum vector  $e(0) = 1 \oplus 0 \oplus 0 \oplus \ldots$  also by  $\Phi$ . The span of all exponential vectors, denoted  $\mathcal{D}$ , forms a dense subspace of  $\mathcal{F}(\mathcal{H})$ .

Let  $\xi$  be a projection (on the Hilbert space H) valued measure on  $\mathbb{R}$  with no jump points, i.e.  $\xi(\{t\}) = 0$  for all  $t \in \mathbb{R}$ . Denote by  $\mathcal{H}_{t]}, \mathcal{H}_{[s,t]}$  and  $\mathcal{H}_{[t}$  the ranges of the projections  $\xi((-\infty,t]), \xi([s,t])$  and  $\xi([t,\infty))$ , respectively. For a vector  $f \in \mathcal{H}$  we denote  $f_{t]} := \xi((-\infty,t])f, f_{[s,t]} := \xi([s,t])f$  and  $f_{[t]} := \xi([t,\infty))f$ . Let us write  $\mathcal{H}$  as the direct sum  $\mathcal{H}_{t]} \oplus \mathcal{H}_{[t]}$ , then  $\mathcal{F}(\mathcal{H})$  is unitarily equivalent with  $\mathcal{F}(\mathcal{H}_{t]}) \otimes \mathcal{F}(\mathcal{H}_{[t]})$  through the identification  $e(f) \cong e(f_{t]}) \otimes e(f_{[t]})$ . For notational convenience the tensor product signs between exponential vectors are often omitted. The algebra  $\mathcal{W} := \mathcal{B}(\mathcal{F}(\mathcal{H}))$  also splits as a tensor product  $\mathcal{W}_{t]} \otimes \mathcal{W}_{[t]}$  where  $\mathcal{W}_{t]} := \mathcal{B}(\mathcal{F}(\mathcal{H}_{t]})$  and  $\mathcal{W}_{[t]} := \mathcal{B}(\mathcal{F}(\mathcal{H}_{[t]}))$ .

A map  $m : \mathbb{R}_+ \to \mathcal{H} : t \mapsto m_t$  is called a  $\xi$ -martingale if  $m_t \in \mathcal{H}_t$  for all t and  $\xi([0,s])m_t = m_s$  for all s < t. For m and m'  $\xi$ -martingales, there exists a complex valued measure (of finite variation on every bounded interval), denoted  $\langle \langle m, m' \rangle \rangle$  on  $\mathbb{R}_+$ , satisfying

$$\langle \langle m, m' \rangle \rangle \big( [0, t] \big) = \langle m_t, m'_t \rangle, \tag{4.6}$$

for all  $t \ge 0$ . Let *m* be a  $\xi$ -martingale. The annihilation operator  $A(m_t)$  and creation operator  $A^*(m_t)$  are defined on the domain  $\mathcal{D}$  by

$$A(m_t)e(g) = \langle m_t, g \rangle e(g), \quad g \in \mathcal{H}, \langle e(h), A^*(m_t)e(g) \rangle_{\mathcal{F}(\mathcal{H})} = \langle h, m_t \rangle \langle e(h), e(g) \rangle_{\mathcal{F}(\mathcal{H})}, \quad h, g \in \mathcal{H}.$$

$$(4.7)$$

Let  $M_t$  be one of the processes  $A(m_t)$  or  $A^*(m_t)$  for some  $\xi$ -martingale m. The following factorisation property [54], [74] makes the definition of stochastic integration against  $M_t$  possible

$$(M_t - M_s)e(f) = e(f_{s})\{(M_t - M_s)e(f_{[s,t]})\}e(f_{[t]}),$$

with  $(M_t - M_s)e(f_{[s,t]}) \in \mathcal{F}(\mathcal{H}_{[s,t]})$ . We first define the stochastic integral for the so-called *simple* operator processes with values in the atom and noise algebra  $\mathcal{B} \otimes \mathcal{W}$  where  $\mathcal{B} := M_n$  and  $\mathcal{W}$  is the algebra of all bounded operators on the Fock space  $\mathcal{F}(\mathcal{H})$ .

**Definition 4.3.1:** Let  $\{L_s\}_{0 \le s \le t}$  be an adapted (i.e.  $L_s \in \mathcal{B} \otimes \mathcal{B}(\mathcal{F}(H_s]))$  for all  $0 \le s \le t$ ) simple process with respect to the partition  $\{s_0 = 0, s_1, \ldots, s_p = t\}$  in the sense that  $L_s = L_{s_j}$  whenever  $s_j \le s < s_{j+1}$ . Then the stochastic integral of L with respect to M on  $\mathbb{C}^n \otimes \mathcal{D}$  is given by [54], [74]:

$$\int_0^t L_s dM_s \ fe(u) := \sum_{j=0}^{p-1} \left( L_{s_j} fe(u_{s_j}]) \right) \left( (M_{s_{j+1}} - M_{s_j}) e(u_{[s_j, s_{j+1}]}) \right) e(u_{[s_{j+1}}) \cdot M_{s_j}) e(u_{[s_j, s_{j+1}]}) = 0$$

By the usual approximation by simple processes we can extend the definition of the stochastic integral to a large class of stochastically integrable processes [54], [74]. We simplify our notation by writing  $dX_t = L_t dM_t$  for  $X_t = X_0 + \int_0^t L_s dM_s$ . Note that the definition of the stochastic integral implies that the increments  $dM_s$  lie in the future, i.e.  $dM_s \in \mathcal{W}_{[s]}$ . Another consequence of the definition of the stochastic integral is that its expectation with respect to the vacuum state  $\langle \Phi, \cdot \Phi \rangle$  is always 0 due to the fact that the increments  $dA(m_t)$  and  $dA^*(m_t)$  have zero expectation values in the vacuum. This will often simplify calculations of expectations, our strategy being that of trying to bring these increments to act on the vacuum state thus eliminating a large number of differentials.

The following theorem of Hudson and Parthasarathy extends the Itô rule of classical probability theory.

**Theorem 4.3.2:** (Quantum Itô rule [54], [74]) Let  $M_1$  and  $M_2$  each be one of the processes  $A(m_t)$  or  $A^*(m'_t)$ . Then  $M_1M_2$  is an adapted process satisfying the relation:

$$d(M_1M_2) = M_1 dM_2 + M_2 dM_1 + dM_1 dM_2,$$

where  $dM_1 dM_2$  is given by the quantum Itô table:

$$\frac{dM_1 \setminus dM_2}{dA^*(m_t)} \quad \frac{dA^*(m_t')}{dA^*(m_t)} \quad \begin{array}{l} dA^*(m_t') \\ 0 \\ dA(m_t) \\ d\langle\langle m, m'\rangle\rangle \end{array} \quad 0$$

**Notation.** The quantum Itô rule will be used for calculating differentials of products of Itô integrals. Let  $\{Z_i\}_{i=1,\dots,p}$  be Itô integrals, then

$$d(Z_1 Z_2 \dots Z_p) = \sum_{\substack{\nu \subset \{1, \dots, p\}\\ \nu \neq \emptyset}} [\nu]$$

where the sum runs over all *non-empty* subsets of  $\{1, \ldots, p\}$  and for any  $\nu = \{i_1, \ldots, i_k\}$ , the term  $[\nu]$  is the contribution to  $d(Z_1Z_2\ldots,Z_p)$  coming from differentiating only the terms with indices in the set  $\{i_1, \ldots, i_k\}$  and preserving the order of the factors in the product. For example the differential  $d(Z_1Z_2Z_3)$  contains terms of the type  $[2] = Z_1(dZ_2)Z_3$ ,  $[13] = (dZ_1)Z_2(dZ_3)$ , and  $[123] = (dZ_1)(dZ_2)(dZ_3)$ .

Let us return to the setup of section 4.2. We now make sense of equation (4.4). Note that the Hilbert space  $\mathcal{H}$  is  $L^2(\mathbb{R}) \oplus L^2(\mathbb{R})$ . The forward and side channel both have their own copy of  $L^2(\mathbb{R})$ . The projection valued measure  $\xi$  is given by

$$\xi(I)(f_f \oplus f_s) = (\chi_I f_f) \oplus (\chi_I f_s), \qquad f_f, f_s \in L^2(\mathbb{R}),$$

for all Borel subsets I of  $\mathbb{R}$ . Here  $\chi_I$  denotes the *indicator function* of I, i.e. the function that takes the value 1 on I and is 0 elsewhere.

The maps  $m^f$ :  $\mathbb{R}_+ \to \mathcal{H}$ :  $t \mapsto \chi_{[0,t]} \oplus 0$  and  $m^s$ :  $\mathbb{R}_+ \to \mathcal{H}$ :  $t \mapsto 0 \oplus \chi_{[0,t]}$ are  $\xi$ -martingales. We denote the annihilation  $A(m_t^f), A(m_t^s)$  and creation operators  $A^*(m_t^f), A^*(m_t^s)$ , defined on  $\mathcal{D}$  by (4.7), more compactly by  $A_f(t), A_s(t), A_f^*(t)$  and  $A_s^*(t)$ , respectively. The calculus for stochastic integrals with respect to  $A_{\sigma}(t)$  and  $A_{\nu}^*(t), \sigma, \nu \in \{f, s\}$  is then given by the Hudson-Parthasarathy Itô table [54], [74]:

$$\begin{array}{c|ccc} dM_1 \backslash dM_2 & dA_{\nu}^*(t) & dA_{\nu}(t) \\ \hline dA_{\sigma}^*(t) & 0 & 0 \\ dA_{\sigma}(t) & \delta_{\sigma\nu} dt & 0 \\ \end{array}$$

Let us introduce the selfadjoint quantum noise  $\beta_t$  describing the interaction between the quantum system  $\mathcal{B} = M_n(\mathbb{C})$  and the electromagnetic field

$$d\beta_t := -i \big( V_f dA_f^*(t) - V_f^* dA_f(t) + V_s dA_s^*(t) - V_s^* dA_s(t) \big), \qquad \beta_0 = 0.$$
(4.8)

It is clear in our example of spontaneous decay of a two-level system that this noise represents an interaction consisting of creations of excitations of the two-level system accompanied by annihilations of photons in the decay channels and vice versa. It describes the interaction of the electromagnetic field, in which we distinguished two decay channels, and the two-level system in the weak coupling limit [2]. We let the cocycle  $U_t$  of section 4.2, providing the evolution in the weak coupling limit of the two-level system and field together, be given by the quantum stochastic differential equation

$$dU_t = \{id\beta_t - \frac{1}{2}(d\beta_t)^2\}U_t = \{V_f dA_f^*(t) - V_f^* dA_f(t) + V_s dA_s^*(t) - V_s^* dA_s(t) - \frac{1}{2}V^*V dt\}U_t, U_0 = \mathbf{1}.$$

We can now check that the dilation diagram (4.5) commutes. Using the continuous tensor product structure of the Fock space  $\mathcal{F}(\mathcal{H})$ , it is easy to see that following the lower part of diagram (4.5) defines a semigroup on  $\mathcal{B}$ , i.e. we only have to show that it is generated by the Lindblad operator L of equation (4.3). For all  $X \in \mathcal{B}$ 

$$d\mathrm{Id} \otimes \phi \otimes \phi(\hat{T}_t(X \otimes \mathbf{1} \otimes \mathbf{1})) = \mathrm{Id} \otimes \phi \otimes \phi(d(U_t^*(X \otimes \mathbf{1} \otimes \mathbf{1}))).$$

Using the notation below Theorem 4.3.2 with  $Z_1 = U_t^*$  and  $Z_2 = (X \otimes \mathbf{1} \otimes \mathbf{1})U_t$ , we find

$$d\mathrm{Id} \otimes \phi \otimes \phi(T_t(X \otimes \mathbf{1} \otimes \mathbf{1})) = \mathrm{Id} \otimes \phi \otimes \phi([1] + [2] + [12]),$$

With the aid of the Hudson-Parthasarathy Itô table we can evaluate these terms. We are only interested in the dt-terms since the expectation with respect to the vacuum kills the other terms. The terms [1] and [2] provide the anticommutators  $-\frac{1}{2}\{V_f^*V_f, X\}dt$  and  $-\frac{1}{2}\{V_s^*V_s, X\}dt$  and [12] provides the terms  $V_f^*XV_fdt$  and  $V_s^*XV_sdt$ , proving our claim.

We now change the situation in diagram (4.5) by introducing a laser on the forward channel, i.e. the forward channel is now in a *coherent state*  $\gamma_h := \langle \psi(h), \cdot \psi(h) \rangle$  where  $\psi(h) := \exp(-\frac{1}{2} \|h\|^2) e(h)$ , the exponential vector e(h) for some  $h \in L^2(\mathbb{R}_+)$  normalised to unity. The laser will be used to send control-pulses to the system  $\mathcal{B}$ . This leads to the following dilation diagram

i.e. the evolution on  $\mathcal{B}$  has changed and it is in general *not* a semigroup. Denote by W(h) the unitary Weyl or displacement operator defined on  $\mathcal{D}$  by:  $W(h)\psi(g) = \exp(-2i\mathrm{Im}\langle h,g\rangle)\psi(g+h)$ . Note that  $W(h)\Phi = W(h)\psi(0) = \psi(h)$ , so that we can write for all  $X \in \mathcal{B}$ 

$$T_t^h(X) = \mathrm{Id} \otimes \gamma_h \otimes \phi(U_t^* X \otimes \mathbf{1} \otimes \mathbf{1} U_t) =$$
  
$$\mathrm{Id} \otimes \phi \otimes \phi(W_f(h)^* U_t^* X \otimes \mathbf{1} \otimes \mathbf{1} U_t W_f(h)) =$$
  
$$\mathrm{Id} \otimes \phi \otimes \phi(W_f(h_t))^* U_t^* X \otimes \mathbf{1} \otimes \mathbf{1} U_t W_f(h_t)),$$

where  $h_{t]} = h\chi_{(0,t]}$  and  $W_f(h) := \mathbf{1} \otimes W(h) \otimes \mathbf{1}$ . Defining  $U_t^h := U_t W_f(h_{t]})$ , together with the quantum stochastic differential equation for  $W_f(h_t)$  [74]

$$dW_f(h_{t]}) = \{h(t)dA_f^*(t) - \overline{h}(t)dA_f(t) - \frac{1}{2}|h(t)|^2dt\}W_f(h_{t]}), \quad W_f(h_{0]}) = \mathbf{1},$$

and the Itô rules leads to the following quantum stochastic differential equation for  $U_t^h$ 

$$dU_t^h = \left\{ \left( V_f + h(t) \right) dA_f^*(t) - \left( V_f^* + \overline{h}(t) \right) dA_f(t) \right) + V_s dA_s^*(t) - V_s^* dA_s(t) - \frac{1}{2} \left( |h(t)|^2 + V^* V + 2h(t) V_f^* \right) dt \right\} U_t^h, \quad U_0^h = \mathbf{1}.$$

$$(4.10)$$

Therefore, the dilation diagram (4.9) is equivalent to

### 4.4. THE BELAVKIN EQUATION

In the following, we will often omit the superscript h to simplify the notation. Define a Hamiltonian by  $H := i(\overline{h}(t)V_f - h(t)V_f^*)$ , then following the lower part of diagram (4.11) and using Itô's rules, see Theorem 4.3.2, shows that the time dependent generator of the dissipative evolution  $T_t^h$  in the presence of the laser on the control channel is given by

$$L(X) = i[H, X] + V^* X V - \frac{1}{2} \{ V^* V, X \}.$$
(4.12)

Later on we will choose h in a suitable way in order to exert control on the system  $\mathcal{B}$ .

## 4.4 The Belavkin equation

Let us now turn our attention to the side channel. In this channel an observable is measured continuously in time. Goal is to briefly show how to derive a stochastic differential equation for the stochastic state evolution of the system  $\mathcal{B}$  conditioned on the outcome of the measurement process. The method described below is known as quantum filtering, see [17] and [23] for a more detailed treatment.

In this paper the observable  $Y_t^s$  of the field that is measured continuously in time will always be a field quadrature, i.e.

$$Y_t^s := \mathbf{1}_{\mathcal{B}} \otimes \mathbf{1}_{W^f} \otimes \left( \left( e^{-i\phi} A_s(t) + e^{i\phi} A_s^*(t) \right) \otimes \mathbf{1}_{\mathcal{W}_{[t]}^s} \right) \in \mathcal{B} \otimes \mathcal{W}^f \otimes \left( \mathcal{W}_{t]}^s \otimes \mathcal{W}_{[t]}^s \right), \quad (4.13)$$

for some phase  $\phi \in [0, 2\pi)$ . Such a field quadrature measurement can be performed by a homodyne detection experiment. See [17], [23] for measurement of other observables. Let  $\rho$  be the initial state of the quantum system  $\mathcal{B}$ . We describe the measurement process in the interaction picture, i.e. the shift part of  $\hat{U}_t := (S_t \otimes S_t)U_t$  acts on the observables while the cocycle part  $U_t$ , given by equation (4.10) with the superscript h suppressed, acts on the states

$$\rho^t(X) := \rho \otimes \phi(U_t^* X U_t), \quad X \in \mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s.$$

Let  $C_t$  be the von Neumann algebra generated by the family of observables  $\{Y_r^s; 0 \le r \le t\}$ . Since  $Y_r^s$  and  $Y_t^s$  commute for all  $r, t \ge 0$  the algebra  $C_t$  is commutative. The algebras  $\{C_t\}_{t\ge 0}$  form a growing family, that is  $C_s \subset C_t$  for all  $s \le t$ . Thus we can define the inductive limit  $C_{\infty} := \lim_{t\to\infty} C_t$ , which is the smallest von Neumann algebra containing all  $C_t$ . It follows via Kolmogorov's extension theorem, see [23] Theorem 5.1, that there exists a unique state  $\rho^{\infty}$  on  $C_{\infty}$  which coincides with  $\rho^t$  when restricted to  $C_t \subset C_{\infty}$  for all  $t \ge 0$ . From spectral theory it follows that there exists a measure space  $(\Omega, \Sigma, \mathbb{P}_{\rho})$  and a growing family  $\{\Sigma_t\}_{t\ge 0}$  of  $\sigma$ -subalgebras of  $\Sigma$ , such that  $(\mathcal{C}_{\infty}, \rho^{\infty})$  and  $(\mathcal{C}_t, \rho^t)$  are isomorphic to  $L^{\infty}(\Omega, \Sigma, \mathbb{P}_{\rho})$  and  $L^{\infty}(\Omega, \Sigma_t, \mathbb{P}_{\rho})$ , respectively. The space  $\Omega$  should be interpreted as the paths of the observed process  $Y_r^s$  when the measurement is continued infinitely long. The  $\sigma$ -algebras  $\Sigma_t$  contain the events up to time t. In the Heisenberg picture, when a measurement of an observable Y with discrete spectrum Sp(Y) has been performed, all observables in  $\mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s$  have to be sandwiched with the projection corresponding to the observed measurement result. If the result of the measurement is unknown, but the measurement has taken place, an observable takes the form of a direct sum over all possible outcomes of the original observable sandwiched with the projections corresponding to the outcomes, i.e.

$$X_{\text{after meas.}} = \bigoplus_{y \in Sp(Y)} P_y X P_y \quad X \in \mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s.$$

Note that this procedure destroys all coherences between different measurement results. Moreover, it maps all observables in  $\mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s$  to the commutant of the algebra generated by the measured observable.

Therefore, in analogy with the above, when a process  $\{Y_r^s\}_{0 \le r \le t}$  has been measured continuosly in time, we can restrict to the algebra  $\mathcal{A}_t \subset \mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s$  which is the *commutant* of the observed process

$$\mathcal{A}_t := \mathcal{C}'_t := \{ X \in \mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s; \ XC = CX, \ \forall C \in \mathcal{C}_t \}.$$

We call  $\mathcal{A}_t$  the algebra of observables that are *not demolished* [17] by observing the process  $\{Y_r^s\}_{0\leq r\leq t}$ . Note that from the double commutant theorem it follows that  $\mathcal{C}_t$  is the *center* of  $\mathcal{A}_t$ , i.e.  $\mathcal{C}_t = \{C \in \mathcal{A}_t; AC = CA, \forall A \in \mathcal{A}_t\}$ .

We investigate the situation of the previous paragraph more abstractly for a moment, i.e. let  $\mathcal{A}$  be a von Neumann algebra of operators on some Hilbert space  $\mathbb{H}$  and let  $\mathcal{C}$  be its center. Let  $\rho$  denote a state on the algebra  $\mathcal{A}$ . We will now explain the decomposition of  $\mathcal{A}$  over its center  $\mathcal{C}$ , see [56] for all details and proofs. We can identify the center  $\mathcal{C}$  with some  $L^{\infty}(\Omega, \Sigma, \mathbb{P})$  where  $\mathbb{P}$  corresponds to the restriction of  $\rho$  to  $\mathcal{C}$ . The Hilbert space  $\mathbb{H}$  has a direct integral representation  $\mathbb{H} = \int^{\oplus} \mathbb{H}_{\omega} \mathbb{P}(d\omega)$  in the sense that there exists a family of Hilbert spaces  $\{\mathbb{H}_{\omega}\}_{\omega\in\Omega}$  and for any  $\psi \in \mathbb{H}$  there exists a map  $\omega \mapsto \psi_{\omega} \in \mathbb{H}_{\omega}$ such that

$$\langle \psi, \phi \rangle = \int_{\Omega} \langle \psi_{\omega}, \phi_{\omega} \rangle \mathbb{P}(d\omega) \quad \psi, \phi \in \mathbb{H}.$$

The von Neumann algebra  $\mathcal{A}$  has a *central decomposition*  $\mathcal{A} = \int^{\oplus} \mathcal{A}_{\omega} \mathbb{P}(d\omega)$  in the sense that there exists a family  $\{\mathcal{A}_{\omega}\}_{\omega\in\Omega}$  of von Neumann algebras with trivial center, or factors, and for any  $A \in \mathcal{A}$  there is a map  $\omega \mapsto A_{\omega} \in \mathcal{A}_{\omega}$  such that  $(A\psi)_{\omega} = A_{\omega}\psi_{\omega}$  for all  $\psi \in \mathbb{H}$ and  $\mathbb{P}$ -almost all  $\omega \in \Omega$ . The state  $\rho$  on  $\mathcal{A}$  has a decomposition in states  $\rho_{\omega}$  on  $\mathcal{A}_{\omega}$ such that for any  $A \in \mathcal{A}$  its expectation is obtained by integrating with respect to  $\mathbb{P}$  the expectations of its components  $A_{\omega}$ :

$$\rho(A) = \int_{\Omega} \rho_{\omega}(A_{\omega}) \mathbb{P}(d\omega).$$

Loosely speaking the component  $A_{\omega} \in \mathcal{A}_{\omega}$  is the operator  $A \in \mathcal{A}$  sandwiched with the projection corresponding to a measurement result  $\omega$ . Moreover, the state  $\rho_{\omega}$  is the state

### 4.4. THE BELAVKIN EQUATION

 $\rho$  conditioned on the measurement result  $\omega$ . For all  $X \in \mathcal{A}$  we denote by  $\rho_{\bullet}(X_{\bullet})$  the function  $\omega \mapsto \rho_{\omega}(X_{\omega})$ . The complex number  $\rho_{\omega}(X_{\omega})$  is the expectation of the observable X in the state  $\rho$  conditioned on measurement result  $\omega$ .

Define a map  $\mathcal{E}_{\rho}$ :  $\mathcal{A} \to \mathcal{C} \cong L^{\infty}(\Omega, \Sigma, \mathbb{P})$  by  $\mathcal{E}_{\rho}(X) := \rho_{\bullet}(X_{\bullet})$  for all  $X \in \mathcal{A}$ . It is easily verified, see also [23], that this map is linear, surjective, identity preserving, completely positive, it satisfies the *module property* 

$$\mathcal{E}_{\rho}(C_1 X C_2) = C_1 \mathcal{E}_{\rho}(X) C_2, \qquad C_1, C_2 \in \mathcal{C}, \ X \in A,$$

and it leaves the state  $\rho$  invariant, i.e.  $\rho(\mathcal{E}_{\rho}(X)) = \rho(X)$  for all  $X \in \mathcal{A}$ . These properties uniquely determine the map  $\mathcal{E}_{\rho}$ , see [84]. It is called the *conditional expectation* of  $\mathcal{A}$  onto  $\mathcal{C}$  with respect to  $\rho$ . Returning to the original problem, i.e. a whole family of algebras  $\mathcal{A}_t$ with center  $\mathcal{C}_t$ , we get a family of conditional expectations  $\mathcal{E}_{\rho^t} : \mathcal{A}_t \to \mathcal{C}_t$ . We denote  $\mathcal{E}_{\rho^t}$ more compactly by  $\mathcal{E}^t$ .

Apart from the family of quantum mechanical conditional expectations  $\mathcal{E}^t$ , there is also a family of conditional expectations in the classical sense that plays an important role in the following. Denote by  $\mathbb{E}_{\rho}^t$  the unique classical conditional expectation from  $\mathcal{C}_{\infty} \cong$  $L^{\infty}(\Omega, \Sigma, \mathbb{P}_{\rho})$  onto  $\mathcal{C}_t \cong L^{\infty}(\Omega, \Sigma_t, \mathbb{P}_{\rho})$  that leaves the state  $\rho^{\infty}$ , or equivalently, the expectation with respect to  $\mathbb{P}_{\rho}$  invariant, i.e.  $\rho^{\infty} \circ \mathbb{E}^t = \rho^{\infty}$ . These conditional expectations satisfy the *tower property*, that is  $\mathbb{E}_{\rho}^s(\mathbb{E}_{\rho}^t(C)) = \mathbb{E}_{\rho}^s(C)$  for all  $C \in \mathcal{C}_{\infty}$  and  $t \ge s \ge 0$ .  $\mathbb{E}_{\rho}^0$ is the expectation with respect to  $\mathbb{P}_{\rho}$  and will simply be denoted  $\mathbb{E}_{\rho}$ . Note that the tower property for s = 0 is just the invariance of the state  $\rho^{\infty}(=\mathbb{E}_{\rho})$ .

For all  $t \geq 0$  and  $X \in \mathcal{B}$  the operator  $X \otimes \mathbf{1} \otimes \mathbf{1} \in \mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s$  commutes with the observed process  $\{Y_r^s\}_{0 \leq r \leq t}$  up to time t, i.e.  $\mathcal{B} \subset \mathcal{A}_t$ . Therefore we can define for all  $X \in \mathcal{B}$  a process  $\{M_t^X\}_{t\geq 0}$  in the algebra  $\mathcal{C}_{\infty} \cong L^{\infty}(\Omega, \Sigma, \mathbb{P}_{\sigma})$  by

$$M_t^X := \mathcal{E}^t(X) - \mathcal{E}^0(X) - \int_0^r \mathcal{E}^r(L(X)) dr, \qquad (4.14)$$

where  $L: \mathcal{B} \to \mathcal{B}$  is the Liouvillian of equation (4.12). From the definition it is clear that  $M_t^X$  is an element of  $\mathcal{C}_t$  for all  $t \ge 0$ . The process  $\{M_t^X\}_{t\ge 0}$  is a martingale, i.e. for all  $0 \le s \le t$  we have  $\mathbb{E}_{\rho}^s(M_t^X) = M_s^X$ , see [17], [23] for details and a proof. In differential form equation (4.14) reads

$$d\rho_{\bullet}^{t}(X) = \rho_{\bullet}^{t}(L(X))dt + dM_{t}^{X},$$

where we have used that  $X_{\bullet}$  is the constant function  $\omega \mapsto X$ . This equation is the *Belavkin* equation [14], [17], [23].

Denote by  $\tilde{Y}_t^s$  the process given by the following stochastic differential equation

$$d\tilde{Y}_t^s = dY_t^s - \mathcal{E}^t(e^{i\phi}V_s^* + e^{-i\phi}V_s)dt, \quad \tilde{Y}_0^s = 0.$$

The process  $\tilde{Y}_t^s$  is a martingale, i.e. for all  $0 \leq r \leq t$  we have  $\mathbb{E}_{\rho}^r(\tilde{Y}_t^s) = \tilde{Y}_r^s$ , see [17], [23] for details and a proof. We call  $\tilde{Y}_t^s$  the *innovating martingale* of the observed process  $Y_t^s$ . The link between the martingale  $M_t^X$  and the observed process  $Y_t^s$  is provided by the martingale representation theorem which states that there exists a stochastically integrable process  $\eta_t^X$  such that

$$dM_t^X = \eta_t^X d\tilde{Y}_t^s = \eta_t^X \left( dY_t^s - \mathcal{E}^t (e^{i\phi} V_s^* + e^{-i\phi} V_s) dt \right).$$

The process  $\eta_t^X$  can be calculated by using that  $\mathcal{E}^t$  leaves  $\rho^t$  invariant [17]. We refer to [23] for the details, the result is

$$\eta_t^X = \mathcal{E}^t(e^{i\phi}V_s^*X + e^{-i\phi}XV_s) - \mathcal{E}^t(e^{i\phi}V_s^* + e^{-i\phi}V_s)\mathcal{E}^t(X).$$

This leads to the Belavkin equation [17], [23]

$$d\rho_{\bullet}^{t}(X) = \rho_{\bullet}^{t}(L(X))dt + \left(\rho_{\bullet}^{t}(e^{i\phi}V_{s}^{*}X + e^{-i\phi}XV_{s}) - \rho_{\bullet}^{t}(e^{i\phi}V_{s}^{*} + e^{-i\phi}V_{s})\rho_{\bullet}^{t}(X)\right) \times \\ \times \left(dY_{t}^{s} - \rho_{\bullet}^{t}(e^{i\phi}V_{s}^{*} + e^{-i\phi_{t}}V_{s})dt\right) \quad X \in \mathcal{B}.$$

$$(4.15)$$

This equation tells us how the state of the system  $\mathcal{B}$  evolves over an infinitesimal time dt depending on what we observe for the measurement process  $dY_t^s$ . Since  $\tilde{Y}_t^s$  is a martingale with variance t on the space of the Wiener process, it must be the Wiener process itself.

# 4.5 Control: the essentially commutative case

In this section we focus on dilations that are essentially commutative [63]. We will use the results of the measurement of  $Y_t^s$  to control the time evolution  $T_t$  of the system  $\mathcal{B}$  in order to bring it as close to the identity map as possible. For essentially commutative dilations this can be done (nearly) perfectly. This section serves as a guiding example for the more realistic situations described in sections 4.6 and 4.8.

Let V be selfadjoint, i.e.  $V = V^*$ . The discussion below can easily be adapted to fit the situation where  $V = -V^*$ . Define for  $\sigma = f, s$  field observables  $Y_t^{\sigma} := i(A_{\sigma}^*(t) - A_{\sigma}(t)) \in \mathcal{W}_{t]}^{\sigma}$ . Using  $V = V^*$ , equation (4.4), i.e. the laser on the forward channel is off, simplifies to

$$dU_t = \left\{ -iV_f dY_t^f - iV_s dY_t^s - \frac{1}{2}V^2 dt \right\} U_t, \qquad U_0 = \mathbf{1}.$$
 (4.16)

This means that for  $t \ge 0$  the solution  $U_t$  is an element of  $\mathcal{B} \otimes \mathcal{C}_t$ , with  $\mathcal{C}_t$  the commutative von Neumann algebra generated by the process  $\{Y_r^f \otimes Y_r^s\}_{0 \le r \le t}$ . (We have dropped the extensive notation with the identities tensored to the  $Y_r$ 's.) This means that we can restrict the dilation of diagram (4.11) to  $\mathcal{B} \otimes \mathcal{C}_{\infty}$ , i.e.

A dilation for which the relative commutant of the embedding of the algebra  $\mathcal{B}$  into the subalgebra of  $\mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}^s$  generated by  $\{U_t^* X \otimes \mathbf{1} \otimes \mathbf{1} U_t; X \in \mathcal{B}, t \geq 0\}$  is commutative, is called *essentially commutative* [63]. Although we restrict the discussion to the essentially commutative dilation determined by equation (4.16), the results of this section can be extended to all essentially commutative dilations [63].

If the dilation is essentially commutative the derivation of the Belavkin equation is extremely simple. Since  $U_t$  is not demolished by observing  $\{Y_r^s\}_{0 \le r \le t}$ , i.e. it is an element of the commutant of  $C_t$ , we can just calculate  $d(U_t^*X \otimes \mathbf{1} \otimes \mathbf{1}U_t)$  using the quantum Itô rules and decompose it over the paths of the measurement process. It is clear that this leads exactly to the Belavkin equation of the previous section (4.15) with  $\phi = \frac{\pi}{2}$  and  $V = V^*$ 

$$d\rho_{\bullet}^t(X) = \rho_{\bullet}^t(L(X))dt + i\rho_{\bullet}^t([V_s, X])dY_t^s, \qquad (4.18)$$

where L is as in equation (4.12) with H is 0, i.e. there has been no control yet. In general, however, we do not have the decomposition of  $U_t$  over the center and we have to resort to the methods of the previous section. Note that for  $\phi = \frac{\pi}{2}$  and  $V = V^*$  we have  $d\tilde{Y}_t^s = dY_t^s$ , i.e.  $Y_t^s$  is the Wiener process. This means that the measurement process is *non-informative* [51], i.e. since here there is no state dependent drift term, we do not gain information about the state  $\rho_{\bullet}^t$  by observing  $Y_t^s$ .

Let  $\rho^0$  be the density matrix of the initial state of the system  $\mathcal{B}$ . We observe  $Y_t^s$  from time 0 to time  $\tau$ . Suppose that the laser is off in that time interval, i.e. h(t) = 0 for  $0 \le t < \tau$ . Then the stochastic density matrix at time  $\tau$  is given by (4.18)

$$\tilde{\rho}_{\bullet}^{\tau} = \rho^0 + \int_0^{\tau} V \tilde{\rho}_{\bullet}^t V^* dt - \frac{1}{2} \{ V^* V, \tilde{\rho}_{\bullet}^t \} dt + i [\tilde{\rho}_{\bullet}^t, V_s] dY_t^s,$$

where the tilde has been introduced to remind us that this is the state *before* control has taken place. In the time interval from 0 to  $\tau$  we have observed  $Y_t^s$  and therefore we can determine the difference  $\Delta(\tau) := Y_{\tau}^s - Y_0^s$  at time  $\tau$ . Then we want to control the state  $\tilde{\rho}_{\bullet}^{\tau}$  with a unitary

$$U_c^{\tau} := \exp\left(i\Delta(\tau)V_s\right)$$

i.e. the density matrix after control is given by  $\rho_{\bullet}^{\tau} = U_c^{\tau} \tilde{\rho}_{\bullet}^{\tau} U_c^{\tau*}$ . This can be done by supplying a very sharply peaked laser pulse to the system, i.e. take

$$h(t) = -i\frac{\kappa_s \Delta(\tau)}{2\kappa_f} \delta_\tau(t), \quad 0 \le t < 2\tau_f$$

where  $\delta_{\tau}$  is the delta function at time  $\tau$ . Then  $H = -\Delta(\tau)\delta_{\tau}V_s$  in equation (4.12), i.e. at time  $\tau$  all terms in equation (4.12) are negligable with respect to the commutator with H. At time  $\tau$  this commutator performs a Rabi oscillation exactly of size  $U_c^{\tau}$ . After having applied the control unitaries the state  $\rho_{\bullet}^{\tau}$  is taken as the new initial state  $\rho^0$  and the control scheme is repeated after every  $\tau$  time units.

Note that the control unitary  $U_c^{\tau}$  satisfies the following stochastic differential equation

$$dU_c^{\tau} = \{iV_s dY_{\tau}^s - \frac{1}{2}V_s^2 d\tau\}U_c^{\tau} = U_c^{\tau}\{iV_s dY_{\tau}^s - \frac{1}{2}V_s^2 d\tau\}, \quad U_c^0 = \mathbf{1}.$$

Recall that we have the Itô rules  $dY_t^s dY_t^s = dt$ ,  $dY_t^s dt = dt dY_t^s = 0$ ,  $dY_t^f dt = dt dY_t^f = 0$  and  $dY_t^s dY_t^f = dY_t^f dY_t^s = 0$ . Using the notation below Theorem 4.3.2 with  $Z_1 = U_c^{\tau}$ ,  $Z_2 = \tilde{\rho}_{\bullet}^{\tau}$  and  $Z_3 = U_c^{\tau*}$  we find infinitesimally at  $\tau = 0$ , i.e.  $\tau$  should be very small or equivalently we should correct with extremely high frequency

$$d\rho_{\bullet}^{\tau}\Big|_{\tau=0} = \left( [1] + [2] + [3] + [12] + [13] + [23] + [123] \right) \Big|_{\tau=0}.$$
 (4.19)

Note that it immediately follows from Itô's rules that [123] = 0.

For  $W \in \mathcal{B}$  we denote by  $L_W$  the Lindblad operator corresponding to W acting on density matrices  $\rho$ , i.e.

$$L_W(\rho) := W\rho W^* - \frac{1}{2} \{ W^* W, \rho \}.$$

Then we can write  $([1]+[3]+[13])|_{\tau=0} = L_{V_s}(\rho^0)d\tau - i[\rho^0, V_s]dY_0^s$  and  $([2]+[12]+[23])|_{\tau=0} = L_V(\rho^0)d\tau + i[\rho^0, V_s]dY_0^s - 2L_{V_s}(\rho^0)d\tau$ . Therefore we get  $d\rho_{\bullet}^{\bullet}|_{\tau=0} = L_{V_f}(\rho^0)d\tau$  and since we repeat the control every  $\tau$  time units with  $\tau$  very small, i.e. we take  $\tau$  infinitesimal, this leads to the following deterministic state evolution

$$d\rho^t = L_{V_f}(\rho^t) dt$$

This means we only have dissipation into the forward channel. We can take  $\kappa_f$  arbitrarily small which means we have succeeded in freezing the state evolution nearly perfectly, i.e. the control scheme *restores quantum information* in the sense of [51].

# 4.6 Control without squeezing

We now return to the more realistic situation of spontaneous decay of a two-level atom to its ground state. We are again interested in controlling the state of a system in order to get as close as possible to freezing its state evolution. However, in trying to do this, we encounter problems that motivate the investigation put forward in the sections to come.

### 4.6. CONTROL WITHOUT SQUEEZING

Guided by the previous section we write V of equation (4.2) as the sum  $V = V_R + iV_I$  with  $V_R$  and  $V_I$  selfadjoint, i.e.

$$V_R := \frac{V + V^*}{2} = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad V_I := \frac{V - V^*}{2i} = \frac{1}{2} \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}.$$
(4.20)

Denote for  $\sigma = f, s: V_R^{\sigma} := \kappa_{\sigma} V_R, V_I^{\sigma} := \kappa_{\sigma} V_I, Y_R^{\sigma}(t) := i (A_{\sigma}^*(t) - A_{\sigma}(t))$  and  $Y_I^{\sigma}(t) := A_{\sigma}^*(t) + A_{\sigma}(t)$ . Then equation (4.4), i.e. the laser is off, can be written as

$$dU_t := \left\{ \left( \sum_{\sigma=f,s} i V_I^{\sigma} dY_I^{\sigma}(t) - i V_R^{\sigma} dY_R^{\sigma}(t) \right) - \frac{1}{2} V^* V dt \right\} U_t, \quad U_0 = \mathbf{1}.$$
(4.21)

Since the noises  $Y_R^s(t)$  and  $Y_I^s(t)$  in the side channel do not commute we can not observe them both simultaneously.

In the following we choose to observe  $Y_R^s(t)$  and to keep notation simple we denote it by  $Y_t$ . The Belavkin equation for observation of  $Y_t$  follows from equation (4.15)

$$d\rho_{\bullet}^{t} = L(\rho_{\bullet}^{t})dt + i\left(\rho_{\bullet}^{t}V_{s}^{*} - V_{s}\rho_{\bullet}^{t} - \operatorname{Tr}(\rho_{\bullet}^{t}V_{s}^{*} - V_{s}\rho_{\bullet}^{t})\rho_{\bullet}^{t}\right) \times \left(dY_{t} - i\operatorname{Tr}(\rho_{\bullet}^{t}V_{s}^{*} - V_{s}\rho_{\bullet}^{t})dt\right).$$

where L is given by equation (4.12) with H = 0. Using the relation  $\rho_{\bullet}^t V_s^* - V_s \rho_{\bullet}^t = [\rho_{\bullet}^t, V_R^s] - i\{\rho_{\bullet}^t, V_I^s\}$ , this equation simplifies to

$$d\rho_{\bullet}^{t} = L(\rho_{\bullet}^{t})dt + \left(i[\rho_{\bullet}^{t}, V_{R}^{s}] + \{\rho_{\bullet}^{t}, V_{I}^{s}\} - 2\operatorname{Tr}(\rho_{\bullet}^{t}V_{I}^{s})\rho_{\bullet}^{t}\right)\left(dY_{t} - 2\operatorname{Tr}(\rho_{\bullet}^{t}V_{I}^{s})dt\right).$$
(4.22)

Note that  $Y_t$  is a Wiener process plus a stochastic drift term that depends on the state of the two-level atom. By observing  $Y_t$  we can estimate this drift term and in this way obtain information about the state  $\rho_{\bullet}^t$ .

We run a control scheme similar to the one in the previous section, i.e. we choose  $h(t) := -i \frac{\kappa_s \Delta(\tau)}{2\kappa_f} \delta_{\tau}(t)$  for  $0 \leq t < 2\tau$ . Then we get a control unitary  $U_c^{\tau} = \exp\left(i\Delta(\tau)V_R^s\right)$ , satisfying the stochastic differential equation

$$dU_c^{\tau} = \{iV_R^s dY_{\tau} - \frac{1}{2}V_R^{s2} d\tau\}U_c^{\tau} = U_c^{\tau}\{iV_R^s dY_{\tau} - \frac{1}{2}V_R^{s2} d\tau\}, \quad U_c^0 = \mathbf{1}.$$

The state after control is again given by  $\rho_{\bullet}^{\tau} := U_c^{\tau} \tilde{\rho}_{\bullet}^{\tau} U_c^{\tau*}$  where  $\tilde{\rho}_{\bullet}^{\tau}$  is given by the Belavkin equation (4.22). We use the notation below Theorem 4.3.2 with  $Z_1 = U_c^{\tau}$ ,  $Z_2 = \tilde{\rho}_{\bullet}^{\tau}$  and  $Z_3 = U_c^{\tau*}$ . For infinitesimal  $\tau$  evaluated at  $\tau = 0$ , this leads to equation (4.19), i.e.

$$d\rho_{\bullet}^{\tau}\Big|_{\tau=0} = \left( [1] + [2] + [3] + [12] + [13] + [23] + [123] \right) \Big|_{\tau=0}$$

Again [123] = 0 and further  $([1] + [3] + [13])|_{\tau=0} = L_{V_R^s}(\rho^0) d\tau - i[\rho^0, V_R^s] dY_0$ . Furthermore we have

$$\begin{aligned} & [2]\Big|_{\tau=0} = L_V(\rho^0) d\tau + \Big(i[\rho^0, V_R^s] + \{\rho^0, V_I^s\} - 2\mathrm{Tr}(\rho^0 V_I^s)\rho^0\Big) \Big(dY_0 - 2\mathrm{Tr}(\rho^0 V_I^s)d\tau\Big),\\ & ([12] + [23])\Big|_{\tau=0} = -2L_{V_R^s}(\rho^0) d\tau + i[V_R^s, \{\rho^0, V_I^s\}]d\tau - 2\mathrm{Tr}(\rho^0 V_I^s)i[V_R^s, \rho^0]d\tau. \end{aligned}$$

A calculation shows that

$$L_V(\rho^0) - L_{V_R^s}(\rho^0) + i[V_R^s, \{\rho^0, V_I^s\}] = L_{V_f}(\rho^0) + L_{V_I^s}(\rho^0) + \frac{i}{2}[V_I^s V_R^s + V_R^s V_I^s, \rho^0].$$

Since for spontaneous decay  $V_I^s V_R^s + V_R^s V_I^s = 0$ , we get

$$d\rho_{\bullet}^{\tau}\Big|_{\tau=0} = L_{V_f}(\rho^0)d\tau + L_{V_I^s}(\rho^0)d\tau + \left(\{\rho^0, V_I^s\} - 2\mathrm{Tr}(\rho^0 V_I^s)\rho^0\right) \left(dY_0 - 2\mathrm{Tr}(\rho^0 V_I^s)d\tau\right).$$

Since we repeat the control every  $\tau$  time units with  $\tau$  very small, i.e. we take  $\tau$  infinitesimal, this leads to the following stochastic time evolution for the density matrix of the two-level atom

$$d\rho_{\bullet}^{t} = L_{V_{f}}(\rho_{\bullet}^{t})dt + L_{V_{I}^{s}}(\rho_{\bullet}^{t})dt + \left(\{\rho_{\bullet}^{t}, V_{I}^{s}\} - 2\mathrm{Tr}(\rho_{\bullet}^{t}V_{I}^{s})\rho_{\bullet}^{t}\right)\left(dY_{t} - 2\mathrm{Tr}(\rho_{\bullet}^{t}V_{I}^{s})dt\right).$$

The first term on the right hand side is harmless, we already encountered it in the previous section, by taking  $\kappa_f$  small enough we can make it as small as we want. The third term is also harmless. Since  $Y_t - \int_0^t 2 \text{Tr}(\rho_{\bullet}^r V_I^s) dr$  is a martingale it vanishes when we average over all possible outcomes for  $Y_t$ . However, the second term reflects the fact that we can not observe  $Y_I^s$  and correct it simultaneously with  $Y_R^s$ . The next sections are devoted to finding a way around this problem.

# 4.7 Squeezed states and their calculus

In this section we drop the assumption that the side channel of the field is initially in the vacuum state. We take a step back and rethink our model for (a channel in) the field. For the vacuum state we are going to end up with the description we have already used this far. Goal of the description below is to incorporate the situation where the initial state of the side channel is a so-called *squeezed* state. In a squeezed state the variance of one of the quadratures  $Y_R^s$  and  $Y_I^s$  decreases while the other one increases as a result of Heisenberg's uncertainty relation. In the next section we will observe the increased quadrature and correct it. The disturbing effect of the other quadrature has decreased as a result of the squeezing.

Let H be the real space of quadratically integrable  $\mathbb{R}^2$ -valued functions on  $\mathbb{R}$ . On H we define a symplectic form  $\sigma : H \times H \to \mathbb{R}$  by

$$\sigma(f,g) := -\int_{\mathbb{R}} \left( f_1 f_2 \right) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} g_1 \\ g_2 \end{pmatrix} d\lambda, \qquad f = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}, \ g = \begin{pmatrix} g_1 \\ g_2 \end{pmatrix} \in H,$$

where  $\lambda$  denotes the Lebesgue measure on  $\mathbb{R}$ . For notational convenience we define

$$J_0 := \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

We will describe (a channel in) the electromagnetic field by the  $C^*$ -algebra of canonical commutation relations  $CCR(H, \sigma)$  over the symplectic space  $(H, \sigma)$ .

The algebra  $CCR(H, \sigma)$  is defined as the C<sup>\*</sup>-algebra generated by abstract elements  $\{W(f); f \in H\}$  satisfying relations

1. 
$$W(f)^* = W(-f), \quad f \in H,$$
  
2.  $W(f)W(g) = \exp(-i\sigma(f,g))W(f+g), \quad f,g \in H.$ 
(4.23)

The second relation is called the Weyl relation. It follows from [81] that the  $C^*$ -algebra  $CCR(H, \sigma)$  exists and moreover that it is unique up to isomorphism. Furthermore it immediately follows from (4.23) that W(f) is unitary for all  $f \in H$ .

Let  $\alpha$ :  $H \times H \to \mathbb{R}$  be a symmetric positive bilinear form satisfying

$$\sigma(f,g)^2 \le \alpha(f,f)\alpha(g,g), \qquad f,g \in H.$$
(4.24)

It is well known (cf. [75]) that if  $\alpha$  satisfies (4.24) then there exists a unique state  $\gamma$  on the C<sup>\*</sup>-algebra  $CCR(H, \sigma)$  satisfying

$$\gamma(W(f)) = \exp\left(-\frac{1}{2}\alpha(f,f)\right), \quad f \in H.$$
(4.25)

Such a state  $\gamma$  on  $CCR(H, \sigma)$  is called a *quasifree* state.

In this paper we focus on a particular class of quasifree states  $\gamma_{nc}$  indexed by a parameter  $n \in \mathbb{R}$  and a complex parameter  $c = a + ib, a, b \in \mathbb{R}$ . These states will turn out to be the squeezed white noise states of the field as they are encountered in quantum optics after a Markov approximation is made (cf. [45]). They are defined through equation (4.25) with a symmetric positive bilinear form  $\alpha_{nc}$  given by [53]

$$\alpha_{nc}(f,g) = \int_{\mathbb{R}} \left( f_1 f_2 \right) \begin{pmatrix} 2n+1+2a & 2b \\ 2b & 2n+1-2a \end{pmatrix} \begin{pmatrix} g_1 \\ g_2 \end{pmatrix} d\lambda, \quad f,g \in H.$$

For notational convenience we define

$$Q_{nc} := \begin{pmatrix} 2n+1+2a & 2b \\ 2b & 2n+1-2a \end{pmatrix}.$$

Condition (4.24) leads to the restrictions  $n(n+1) \ge |c|^2$  and  $n \ge 0$ . For n = c = 0 we get the usual *vacuum state* and for c = 0 we end up with a chaotic temperature state. More details on the interpretation of this class of states will follow below.

A real linear map  $J : H \to H$  is called *multiplication by* i if it satisfies  $J^2 = -id$ . Then H is a complex vector space with the usual addition and the scalar multiplication given by (x + iy)f = xf + yJf for all  $x, y \in \mathbb{R}$ .

**Lemma 4.7.1:** Let  $n \ge 0$  and  $n(n+1) \ge |c|^2$ . *H* can be considered as a complex vector space equipped with an inner product given by

$$\langle f, g \rangle_{nc} = \alpha_{nc}(f, g) + i\sigma(f, g), \qquad f, g \in H,$$

$$(4.26)$$

if and only if  $n(n+1) = |c|^2$ . In this case multiplication by *i* is given by  $J_{nc} = J_0 Q_{nc}$ .

Proof. Since the inner product (4.26) is linear in its second argument  $J_{nc}$  has to satisfy  $\sigma(f, J_{nc}g) = \alpha_{nc}(f, g)$  for all  $f, g \in H$ . It easily follows from  $n \ge 0$  and  $n(n+1) \ge |c|^2$  that  $Q_{nc}$  is non degenerate. Therefore  $J_{nc}$  has to satisfy  $-J_0J_{nc} = Q_{nc}$  which is equivalent to  $J_{nc} = J_0Q_{nc}$ .  $J_{nc}$  is multiplication by *i* if and only if  $J_{nc}^2 = -id$ , which is equivalent to

$$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 2n+1+2a & 2b \\ 2b & 2n+1-2a \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 2n+1+2a & 2b \\ 2b & 2n+1-2a \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \iff \begin{pmatrix} 4b^2 - (2n+1+2a)(2n+1-2a) & 0 \\ 0 & 4b^2 - (2n+1+2a)(2n+1-2a) \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \iff |c|^2 = n^2 + n.$$

In the following we will always be in the situation of Lemma 4.7.1, i.e.  $n \ge 0$  and  $n(n+1) = |c|^2$ . The states of Lemma 4.7.1, i.e. states that allow for the definition of an inner product on H through (4.26), are called *Fock states* (name will become apparent in a minute). We denote the complex Hilbert space given by the pair  $(H, J_{nc})$  equipped with the inner product of (4.26) by  $H_{nc}$ . Note that  $H_{00}$  is just the space  $L^2(\mathbb{R})$  of all quadratically integrable functions on the real line  $\mathbb{R}$ . The representation of  $CCR(H, \sigma)$  discussed below is actually the GNS-representation with respect to a Fock state  $\gamma_{nc}$ , see [75] for the details.

Fix  $n \ge 0$  and  $c \in \mathbb{C}$  such that  $n(n+1) = |c|^2$ . Recall that the bosonic Fock space over  $H_{nc}$  was defined as

$$\mathcal{F}_{nc} := \mathbb{C} \oplus \bigoplus_{k=1}^{\infty} H_{nc}^{\otimes_s k},$$

and that for all f in  $H_{nc}$  the exponential vector is given by  $e(f) := 1 \oplus \bigoplus_{k=1}^{\infty} \frac{1}{\sqrt{k!}} f^{\otimes k}$ . The span of all exponential vectors was denoted  $\mathcal{D}$  and the vacuum vector  $e(0) = 1 \oplus 0 \oplus 0 \oplus \ldots$ 

was also written as  $\Phi$ . On the dense domain  $\mathcal{D}$  we define for all  $f \in H_{nc}$  operators  $W_{nc}(f)$  by

$$W_{nc}(f)e(g) := \exp\left(-\langle f, g \rangle_{nc} - \frac{1}{2}\alpha_{nc}(f, f)\right)e(f+g), \quad f, g \in H_{nc}$$

They are isometric and therefore uniquely extend to unitary operators on  $\mathcal{F}_{nc}$ . The mapping  $\Pi_{nc}$ :  $W(f) \mapsto W_{nc}(f)$  uniquely defines a linear map  $\Pi_{nc}$  from  $CCR(H, \sigma)$  into the bounded operators on the bosonic Fock space. The map  $\Pi_{nc}$  preserves the relations 1. and 2. of (4.23) defining  $CCR(H, \sigma)$ , i.e. it is a representation of the canonical commutation relations on  $\mathcal{F}_{nc}$ . The state  $\gamma_{nc}$  is now given by the vector  $\Phi \in \mathcal{F}_{nc}$ , i.e.

$$\gamma_{nc}(X) = \langle \Phi, \Pi_{nc}(X)\Phi \rangle_{nc}, \quad X \in CCR(H, \sigma).$$

The triple  $(\mathcal{F}_{nc}, \Pi_{nc}, \Phi)$  is the GNS-triple corresponding to the state  $\gamma_{nc}$ , cf. [75]. The algebra of observables for the electromagnetic field in the Fock state  $\gamma_{nc}$  is modelled by the von Neumann algebra  $\mathcal{W}_{nc}$  generated by  $\{W_{nc}(f); f \in H_{nc}\}$ , which is just all bounded operators on  $\mathcal{F}_{nc}$ .

**Remark.** We can reduce the case of a non Fock quasifree state to a Fock state by doubling the space H to  $H \oplus H$ . We can embed the algebra of canonical commutation relations over H into the algebra of canonical commutation relations over  $H \oplus H$  and view the state on  $CCR(H, \sigma)$  as the restriction of a Fock state on this bigger algebra (cf. [75]). In this way we get representations on a doubled up Fock space. Then the algebra of observables is not the whole algebra of bounded operators but a true subalgebra.

The dilation of the semigroup  $T_t$  of diagram (4.5) serves as our starting point. We change it by replacing the vacuum state  $\phi = \gamma_{00}$  on the side channel by the Fock state  $\gamma_{nc}$  described above. The dilation diagram then changes to

Coupling the quantum system to a field in another state than the vacuum has changed its reduced dynamics to  $T_t^{nc}$ . Changing the representation space of the algebra of canonical commutation relations from  $\mathcal{F} = \mathcal{F}_{00}$  to  $\mathcal{F}_{nc}$  also means that we have to describe the joint evolution of the system and (the two channels in) the field in this representation. Making sense of the group  $\hat{T}_t^{nc}$  will be our main concern for the remainder of this section.

For all  $f \in H$  the family of operators  $\{W_{nc}(tf)\}_{t \in \mathbb{R}}$  forms a one-parameter group, continuous in the strong operator topology. Therefore it follows from Stone's theorem that for all  $f \in H$  there exists a selfadjoint  $B_{nc}(f)$  such that

$$W_{nc}(tf) = \exp\left(itB_{nc}(f)\right)$$

The operators  $B_{nc}(f)$  are called *field operators*. The domain of the operator  $B_{nc}(f_k) \dots B_{nc}(f_1)$  contains  $\mathcal{D}$  for every  $f_1, \dots, f_k \in H$  and  $k \in \mathbb{N}$  (cf. [75]). For  $f, g \in H$  and  $t \in \mathbb{R}$  it follows from the Weyl relation that on the domain  $\mathcal{D}$ 

1. 
$$B_{nc}(tf) = tB_{nc}(f),$$
  
2.  $B_{nc}(f+g) = B_{nc}(f) + B_{nc}(g),$  (4.28)  
3.  $[B_{nc}(f), B_{nc}(g)] = 2i\sigma(f, g).$ 

Let  $H_0$  be the real Hilbert space  $\{f \in H; f = (f_1, 0)\}$ . From (4.28.3) it immediately follows that the family of operators  $\{B_{nc}(f); f \in H_0\}$  is commutative. Using spectral theory, they can be realised as random variables on a single measure space. If the field described by the algebra  $CCR(H, \sigma)$  is in the Fock state  $\gamma_{nc}$ , then the joint characteristic function of the random variables  $B_{nc}(f_1), B_{nc}(f_2), \ldots, B_{nc}(f_k)$  is for  $t_1, \ldots, t_k \in \mathbb{R}$  given by

$$\left\langle \Phi, \exp\left(it_1B_{nc}(f_1)\right) \exp\left(it_2B_{nc}(f_2)\right) \dots \exp\left(it_kB_{nc}(f_k)\right)\Phi \right\rangle = \left\langle \Phi, \exp\left(i\sum_{i=1}^k t_iB_{nc}(f_i)\right)\Phi \right\rangle = \gamma_{nc}\left(W\left(\sum_{i=1}^k t_if_i\right)\right) = \exp\left(-\frac{1}{2}\sum_{i,j=1}^k t_it_j\alpha_{nc}(f_i,f_j)\right),$$

i.e. their joint distribution is Gaussian with covariance matrix  $\alpha_{nc}(f_i, f_j)$ . In a similar way it can be shown that the family  $\{B_{nc}(J_0f); f \in H_0\}$  is commutative and the joint distribution of the random variables  $B_{nc}(J_0f_1), \ldots B_{nc}(J_0f_k)$  is Gaussian with covariance matrix  $\alpha_{nc}(J_0f_i, J_0f_j)$ . The Gaussianity of these fields, the covariance matrix and the condition  $|c|^2 = n^2 + n$  are exactly the defining properties of a squeezed vacuum state in the quantum optics literature, cf. [45].

**Definition 4.7.2:** Fix  $n \in \mathbb{R}$  and  $c \in \mathbb{C}$  such that  $|c|^2 = n^2 + n$ . On the domain  $\mathcal{D} \subset \mathcal{F}_{nc}$  we define *creation* and *annihilation* operators by

$$\begin{aligned} A_{nc}^{*}(f) &:= \frac{1}{2} \big( B_{nc}(f) - i B_{nc}(J_{nc}f) \big), \quad A_{nc}(f) &:= \frac{1}{2} \big( B_{nc}(f) + i B_{nc}(J_{nc}f) \big), \quad f \in H, \\ A_{0}^{*}(f) &:= \frac{1}{2} \big( B_{nc}(f) - i B_{nc}(J_{0}f) \big), \qquad A_{0}(f) &:= \frac{1}{2} \big( B_{nc}(f) + i B_{nc}(J_{0}f) \big), \quad f \in H. \end{aligned}$$

It immediately follows from equation (4.28.3) that these operators satisfy the following commutation relations  $[A_0(f), A_0(g)] = [A_0^*(f), A_0^*(g)] = [A_{nc}(f), A_{nc}(g)] = [A_{nc}^*(f), A_{nc}^*(g)]$ = 0,  $[A_{nc}(f), A_{nc}^*(g)] = \langle f, g \rangle_{nc}$  and  $[A_0(f), A_0^*(g)] = \langle f, g \rangle_{00}$  for all  $f, g \in H$ . Moreover, it is a standard result (cf. [75]) that for Fock states  $A_{nc}(f)\Phi = 0, f \in H$ . Furthermore, we can build up the symmetric Fock space by acting with creation operators on the vacuum. From all these properties it easily follows that for all  $h, f, g \in H$ 

$$A_{nc}(f)e(g) = \langle f,g \rangle_{nc}e(g), \quad \text{and} \quad \left\langle e(h), A_{nc}^*(f)e(g) \right\rangle_{\mathcal{F}_{nc}} = \langle h,f \rangle_{nc} \left\langle e(h), e(g) \right\rangle_{\mathcal{F}_{nc}},$$

i.e.  $A_{nc}(f)$  and  $A_{nc}^*(f)$  satisfy the relations of section 4.3. This means we can define stochastic integrals with respect to  $A_{nc}$  and  $A_{nc}^*$ .

Define the following (non-atomic) projection valued measure  $\xi$  on the direct sum Hilbert space  $\mathcal{H} = L^2(\mathbb{R}) \oplus H_{nc}$  consisting of a copy of  $L^2(\mathbb{R})$  for the forward channel and a copy of  $H_{nc}$  for the side channel by

$$\xi(I): L^2(\mathbb{R}) \oplus H_{nc} \to L^2(\mathbb{R}) \oplus H_{nc}: g \oplus \begin{pmatrix} f_1 \\ f_2 \end{pmatrix} \mapsto g\chi_I \oplus \begin{pmatrix} f_1\chi_I \\ f_2\chi_I \end{pmatrix},$$

for all Borel subsets I of  $\mathbb{R}$ . Here  $\chi_I$  denotes the indicator function of the set I. Define  $\xi$ -martingales by

$$m^{f}: \mathbb{R}_{+} \to \mathcal{H}: t \mapsto m^{f}_{t} := \chi_{[0,t]} \oplus \begin{pmatrix} 0\\0 \end{pmatrix},$$
$$m^{s}: \mathbb{R}_{+} \to \mathcal{H}: t \mapsto m^{s}_{t} := 0 \oplus \begin{pmatrix} \chi_{[0,t]}\\0 \end{pmatrix}.$$

The measure  $\langle \langle m^s, m^s \rangle \rangle$  is then given by  $\langle \langle m^s, m^s \rangle \rangle ([0,t]) = \langle m_t^s, m_t^s \rangle_{nc} = (2n+1+2a)t$ . For  $A_{nc} \left(\frac{m_t^s}{\sqrt{2n+1+2a}}\right)$  and  $A_{nc}^* \left(\frac{m_t^s}{\sqrt{2n+1+2a}}\right)$  we introduce the shorthand notation  $A_s(t)$  and  $A_s^*(t)$ , respectively. Note that for stochastic integrals with respect to  $A_s(t)$  and  $A_s^*(t)$  we find the Hudson-Parthasarathy Itô table. We denote  $A_0(m_t^s)$  and  $A_0^*(m_t^s)$  more compactly by  $A_0(t)$  and  $A_0^*(t)$ . The following lemma enables the definition of stochastic integrals with respect to  $A_0(t)$  and  $A_0^*(t)$ .

**Lemma 4.7.3:** Let  $n \in \mathbb{R}$  and  $c \in \mathbb{C}$  such that  $n(n+1) = |c|^2$ . Then for all  $t \ge 0$  we can write  $A_0(t)$  and  $A_0^*(t)$  as the following linear combinations of  $A_s(t)$  and  $A_s^*(t)$ 

$$A_{0}(t) = \frac{n+c}{\sqrt{2n+1+2a}} A_{s}^{*}(t) + \frac{n+1+c}{\sqrt{2n+1+2a}} A_{s}(t),$$
  
$$A_{0}^{*}(t) = \frac{n+\overline{c}}{\sqrt{2n+1+2a}} A_{s}(t) + \frac{n+1+\overline{c}}{\sqrt{2n+1+2a}} A_{s}^{*}(t),$$

where a is the real part of c.

*Proof.* From Definition 4.7.2 and  $J_{nc} = J_0 Q_{nc}$  it follows that for all  $f \in H$ 

$$A_0(f) = \frac{1}{2} \left( B_{nc}(f) + i B_{nc}(J_0 f) \right) = \frac{1}{2} \left( B_{nc}(f) + i B_{nc}(J_{nc}Q_{nc}^{-1}f) \right)$$
$$= \frac{1}{2} \left( A_{nc}^*(f) + A_{nc}(f) - A_{nc}^*(Q_{nc}^{-1}f) + A_{nc}(Q_{nc}^{-1}f) \right).$$

Using  $J_{nc} = J_0 Q_{nc}$  and

$$Q_{nc}^{-1} = \begin{pmatrix} \frac{1+4b^2}{2n+1+2a} & -2b\\ -2b & 2n+1+2a \end{pmatrix},$$

we find for the  $\xi$ -martingale  $m_t$ 

$$Q_{nc}^{-1}m_t = \begin{pmatrix} \frac{1+4b^2}{2n+1+2a}\chi_{[0,t]} \\ -2b\chi_{[0,t]} \end{pmatrix} = \frac{1}{2n+1+2a} \begin{pmatrix} \chi_{[0,t]} \\ 0 \end{pmatrix} - \frac{2b}{2n+1+2a} J_{nc} \begin{pmatrix} \chi_{[0,t]} \\ 0 \end{pmatrix}$$
$$= \left(\frac{1}{2n+1+2a} - \frac{2b}{2n+1+2a} J_{nc}\right)m_t.$$

From Definition 4.7.2 and equation (4.28) we see that  $A_{nc}(J_{nc}f) = -iA_{nc}(f)$  and  $A_{nc}^*(J_{nc}f) = iA_{nc}^*(f)$  for all  $f \in H$ . Therefore it follows that

$$A_{0}(t) = \frac{1}{2} \left( A_{nc}^{*}(m_{t}) + A_{nc}(m_{t}) - \left(\frac{1}{2n+1+2a} - \frac{2bi}{2n+1+2a}\right) A_{nc}^{*}(m_{t}) + \left(\frac{1}{2n+1+2a} + \frac{2bi}{2n+1+2a}\right) A_{nc}(m_{t}) \right) = \frac{n+c}{2n+1+2a} A_{nc}^{*}(m_{t}) + \frac{n+1+c}{2n+1+2a} A_{nc}(m_{t}) = \frac{n+c}{\sqrt{2n+1+2a}} A_{s}^{*}(t) + \frac{n+1+c}{\sqrt{2n+1+2a}} A_{s}(t).$$

Clearly, we now define for all stochastically integrable processes  $L_t$  stochastic integrals  $L_t dA_0(t)$  and  $L_t dA_0^*(t)$  by  $L_t \frac{n+c}{\sqrt{2n+1+2a}} dA_s^*(t) + L_t \frac{n+1+c}{\sqrt{2n+1+2a}} dA_s(t)$  and  $L_t \frac{n+\overline{c}}{\sqrt{2n+1+2a}} dA_s(t) + L_t \frac{n+1+\overline{c}}{\sqrt{2n+1+2a}} dA_s^*(t)$ , respectively. Using the Hudson-Parthasarathy Itô table it easily follows that the calculus of these stochastic integrals is given by the squeezed noise Itô table [45], [53]:

$dM_1 \backslash dM_2$	$dA_0^*(t)$	$dA_0(t)$
$dA_0^*(t)$	$\overline{c}dt$	ndt
$dA_0(t)$	(n+1)dt	cdt

We are now in a position to explain the construction of  $\hat{T}_t^{nc}$  in the dilation diagram (4.27). The free evolution of the side channel is again given by the unitary group  $S_t$ , the second quantization of the left shift s(t) on  $H_{nc}$ , i.e.

$$s(t)\begin{pmatrix}f_1\\f_2\end{pmatrix} = \begin{pmatrix}f_1(\cdot+t)\\f_2(\cdot+t)\end{pmatrix}, \qquad \begin{pmatrix}f_1\\f_2\end{pmatrix} \in H_{nc}.$$

In the Heisenberg picture the free evolution on  $\mathcal{W}_{nc}$  is then given by  $X \mapsto S_t^* X S_t$ . The system  $\mathcal{B}$  and field together form a closed system, thus their joint evolution is given by a one-parameter group  $\hat{U}_t$  of unitaries, leading to a Heisenberg picture evolution  $\hat{T}_t^{nc} := \operatorname{Ad}[\hat{U}_t]$  on  $\mathcal{B} \otimes \mathcal{W}^f \otimes \mathcal{W}_{nc}^s$ . The group  $\hat{U}_t$  is a perturbation of the free evolution. As in the vacuum case of section 4.2, we let this perturbation be given by the cocycle of unitaries

### 4.8. CONTROL WITH SQUEEZING

 $U_t := (S_{-t} \otimes S_{-t})\hat{U}_t$ . The stochastic differential equation (4.4) that was satisfied by the cocycle  $U_t$  when the side channel was still in the vacuum state is now changed. The quantum noise of equation (4.8) takes the form

$$d\beta_t = -i \big( V_f dA_f(t) - V_f^* dA_f(t) + V_s dA_0^*(t) - V_s^* dA_0(t) \big), \qquad \beta_0 = 0,$$

in the squeezed noise representation. If the field is in the vacuum state the operators  $A_0(t)$  and  $A_s(t)$  coincide.  $A_0(t)$  should be interpreted as the annihilation operator of a photon in the side channel and  $A_s(t)$  should be interpreted as the annihilation operator of a squeezed excitation of in the side channel, i.e. a quasiparticle consisting out of many photons. Using Lemma 4.7.3 we find

$$id\beta_t = V_f dA_f^*(t) - V_f^* dA_f(t) + \left(\frac{n+1+\overline{c}}{\sqrt{2n+1+2a}}V_s - \frac{n+c}{\sqrt{2n+1+2a}}V_s^*\right) dA_s^*(t) - \left(\frac{n+1+c}{\sqrt{2n+1+2a}}V_s^* - \frac{n+\overline{c}}{\sqrt{2n+1+2a}}V_s\right) dA_s(t).$$

Define

$$V_{nc} := \frac{n+1+\overline{c}}{\sqrt{2n+1+2a}} V_s - \frac{n+c}{\sqrt{2n+1+2a}} V_s^*, \tag{4.29}$$

then the quantum stochastic differential equation for the cocycle  $U_t$  is given by

$$dU_t = \{V_f dA_f^*(t) - V_f^* dA_f(t) + V_{nc} dA_s^*(t) - V_{nc}^* dA_s(t) - \frac{1}{2} (V_{nc}^* V_{nc} + V_f^* V_f) dt \} U_t,$$
  

$$U_0 = \mathbf{1}.$$
(4.30)

In a similar way as in section 4.3 this leads to the Lindblad operator for the semigroup  $T_t^{nc} = \exp(tL_{nc})$ :

$$L_{nc}(X) = V_f^* X V_f - \frac{1}{2} \{ V_f^* V_f, X \} + V_{nc}^* X V_{nc} - \frac{1}{2} \{ V_{nc}^* V_{nc}, X \}, \qquad X \in \mathcal{B}.$$

## 4.8 Control with squeezing

Note that the operator  $V_{nc}$  of equation (4.29) for strongly squeezed fields, i.e. n and c are big, is very close to being skew-selfadjoint. Therefore for strongly squeezed fields the dilation is very close to being essentially commutative. In this section we exploit this idea and control the skew-selfadjoint part of  $V_{nc}$ .

Write again  $V = V_R + iV_I$  with  $V_R$  and  $V_I$  the selfadjoint operators of equation (4.20). We will again use for  $X \in \{R, I\}$  and  $\sigma \in \{f, s\}$  the notation  $V_X^{\sigma} := \kappa_{\sigma} V_X$ . Furthermore we introduce:

$$W_R := \frac{V_R^s}{\sqrt{2n+1+2a}} \text{ and } W_I := \frac{V_I^s + i(n+c)V_s^* - i(n+\bar{c})V_s}{\sqrt{2n+1+2a}},$$

i.e.  $V_{nc} = W_R + iW_I$  with  $W_R$  and  $W_I$  selfadjoint. Defining  $Y_R^{\sigma}(t) := i(A_{\sigma}^*(t) - A_{\sigma}(t))$  and  $Y_I^{\sigma}(t) := A_{\sigma}^*(t) + A_{\sigma}(t), \ \sigma \in \{f, s\}$  equation (4.30), i.e. the laser is off, becomes

$$dU_t = \left\{ iV_I^f dY_I^f - iV_R^f dY_R^f + iW_I dY_I^s(t) - iW_R dY_R^s(t) - \frac{1}{2} \left( V_f^* V_f + V_{nc}^* V_{nc} \right) dt \right\} U_t,$$
  
$$U_0 = \mathbf{1}.$$

Using a homodyne detection scheme we can observe the quadratures  $X_{\phi}(t) := e^{-i\phi}A_0(t) + e^{i\phi}A_0^*(t)$  for  $\phi \in [0, 2\pi)$ . With the help of Lemma 4.7.3 this can be written as

$$X_{\phi}(t) = \frac{e^{-i\phi}(n+c) + e^{i\phi}(n+1+\overline{c})}{\sqrt{2n+1+2a}} A_s^*(t) + \frac{e^{-i\phi}(n+1+c) + e^{i\phi}(n+\overline{c})}{\sqrt{2n+1+2a}} A_s(t).$$

For simplicity we assume that c is real, i.e. c = a. Note that the variance of  $X_0$  has increased due to the squeezing, while the variance of  $X_{\frac{\pi}{2}}$  has decreased. Therefore we choose to observe  $Y_t := X_0(t) = \sqrt{2n + 1 + 2a}Y_I^s(t)$ .

The Belavkin equation for observing  $Y_t$  when the laser is still off, follows from equation (4.15) (cf. [94])

$$d\rho_{\bullet}^{t} = L_{nc}(\rho_{\bullet}^{t})dt + \frac{i[W_{I},\rho_{\bullet}^{t}] + \{W_{R},\rho_{\bullet}^{t}\} - 2\mathrm{Tr}\left(\rho_{\bullet}^{t}W_{R}\right)\rho_{\bullet}^{t}}{\sqrt{2n+1+2a}}\left(dY_{t} - 2\mathrm{Tr}\left(\rho_{\bullet}^{t}V_{R}^{s}\right)dt\right).$$
(4.31)

Note that the observed process  $Y_t$  is a drift, represented by the term  $2\text{Tr}(\rho_t^{\bullet}V_R^s)dt$  plus an amplified Wiener process, i.e. amplified up to a variance of (2n + 1 + 2a)t. Through the drift term we gain information on the state of the two-level system. However, for strong squeezing, i.e. n and a big, this information gets lost in the noise of the amplified Wiener process. In the limit for squeezing to infinity, the measurement scheme is again non-informative, just as in the essentially commutative case.

We run a control scheme as in section 4.6 only now based on the observation of  $Y_t$ . We correct with the control unitary given by

$$U_c^{\tau} = \exp\Big(-i\frac{\Delta(\tau)W_I}{\sqrt{2n+1+2a}}\Big),\,$$

where  $\Delta(\tau) := Y_{\tau} - Y_0$ . Note that for c real, i.e. c = a we have

$$W_I = \frac{i\kappa_s\sqrt{2n+1+2a}}{2} \begin{pmatrix} 0 & 1\\ -1 & 0 \end{pmatrix} = \sqrt{2n+1+2a}V_I^s,$$

i.e. we can realise this control unitary by applying a laser pulse determined by  $h(t) = \frac{\kappa_s \Delta(\tau)}{2\kappa_f} \delta_{\tau}(t)$  for  $0 \le t < 2\tau$ . The control unitary satisfies the following quantum stochastic differential equation

$$dU_c^{\tau} = \{-iV_I^s dY_{\tau} - \frac{2n+1+2a}{2}V_I^{s2} d\tau\}U_c^{\tau} = U_c^{\tau}\{-iV_I^s dY_{\tau} - \frac{2n+1+2a}{2}V_I^{s2} d\tau\},$$
  
$$U_c^0 = \mathbf{1}.$$

### 4.8. CONTROL WITH SQUEEZING

The state after control is again given by  $\rho_{\bullet}^{\tau} := U_c^{\tau} \tilde{\rho}_{\bullet}^{\tau} U_c^{\tau*}$  where  $\tilde{\rho}_{\bullet}^{\tau}$  is given by the Belavkin equation (4.31). We use the notation below Theorem 4.3.2 with  $Z_1 = U_c^{\tau}$ ,  $Z_2 = \tilde{\rho}_{\bullet}^{\tau}$  and  $Z_3 = U_c^{\tau*}$ . For infinitesimal  $\tau$  evaluated at  $\tau = 0$ , this leads to equation (4.19), i.e.

$$d\rho_{\bullet}^{\tau}\Big|_{\tau=0} = \left( [1] + [2] + [3] + [12] + [13] + [23] + [123] \right) \Big|_{\tau=0}$$

Again [123] = 0 and further  $([1] + [3] + [13])|_{\tau=0} = L_{W_I}(\rho^0) d\tau + i[\rho^0, V_I^s] dY_0$ . Furthermore we have

$$\begin{aligned} & [2]\Big|_{\tau=0} = L_{nc}(\rho^0)d\tau + \Big(i[V_I^s,\rho^0] + \frac{\{V_R^s,\rho^0\} - 2\mathrm{Tr}\big(\rho^0 V_R^s\big)\rho^0}{2n+1+2a}\Big)\Big(dY_0 - 2\mathrm{Tr}(\rho^0 V_R^s)d\tau\Big),\\ & \big([12] + [23]\big)\Big|_{\tau=0} = -2L_{W_I}(\rho^0)d\tau - i\big[W_I,\{W_R,\rho^0\}\big]d\tau + 2\mathrm{Tr}\big(\rho^0 W_R\big)i[W_I,\rho^0]d\tau. \end{aligned}$$

A calculation shows that

$$L_{nc}(\rho^{0}) - L_{W_{I}}(\rho^{0}) - i[W_{I}, \{W_{R}, \rho^{0}\}] = L_{V_{f}}(\rho^{0}) + L_{W_{R}}(\rho^{0}) - \frac{i}{2}[W_{I}W_{R} + W_{R}W_{I}, \rho^{0}].$$

Since  $W_I W_R + W_R W_I = 0$  for real c and  $\operatorname{Tr}(\rho^0 W_R)[W_I, \rho^0] = \operatorname{Tr}(\rho^0 V_R^s)[V_I^s, \rho^0]$ , we get

$$d\rho_{\bullet}^{\tau}\Big|_{\tau=0} = L_{V_f}(\rho^0)d\tau + L_{W_R}(\rho^0)d\tau + \left(\frac{\{V_R^s, \rho^0\} - 2\mathrm{Tr}(\rho^0 V_R^s)\rho^0}{2n+1+2a}\right) \left(dY_0 - 2\mathrm{Tr}(\rho^0 V_R^s)d\tau\right).$$

Since we repeat the control every  $\tau$  time units with  $\tau$  very small, i.e. we take  $\tau$  infinitesimal, this leads to the following stochastic time evolution for the density matrix of the two-level atom

$$d\rho_{\bullet}^{t} = L_{V_{f}}(\rho_{\bullet}^{t})dt + \frac{L_{V_{R}^{s}}(\rho_{\bullet}^{t})}{2n+1+2a}dt + \Big(\frac{\{V_{R}^{s},\rho_{\bullet}^{t}\} - 2\mathrm{Tr}(\rho_{\bullet}^{t}V_{R}^{s})\rho_{\bullet}^{t}}{2n+1+2a}\Big)\Big(dY_{t} - 2\mathrm{Tr}(\rho_{\bullet}^{t}V_{R}^{s})dt\Big).$$

The first term on the right hand side is again due to the fact that we did not measure and correct the forward channel. It is harmless, since we can take  $\kappa_f$  arbitrarily small. The other two terms converge to 0 when squeezing goes to infinity. Therefore, in the limit, this control scheme restores quantum information.

# Summary

In this thesis the time evolution of open quantum systems is studied. We focus on the time evolution of the state of the system conditioned on the result of some measurement performed continuously in time in its environment. The goal is to derive a stochastic differential equation for the conditional state in which the observed measurement process is a stochastic driving term.

The derivation is carried out within the framework of *non-commutative* or *quantum* probability theory. In this generalised probability theory there exists a non-commutative generalisation of Itô's stochastic calculus. The interaction between an open system and the quantized electromagnetic field in the weak coupling limit is governed by a stochastic differential equation in this non-commutative sense. The stochastic differential equation for the conditional state can be derived from it. It is interpreted as a non-commutative generalisation of the Kushner-Stratonovich filtering equation and is called the Belavkin filtering equation.

In Chapter 2 we study a photon counting experiment. The open system studied here, is a two-level atom driven by a laser. It emits fluorescence photons in its environment, the electromagnetic field. The emitted photons are detected continuously in time. We explicitly condition on the observed event by sanwiching with the corresponding projection in the field. Using the processes introduced by Davies [33], this leads to a continuous time evolution of the reduced system, i.e. the two-level atom, interrupted by jumps at the moments at which photons are detected. In quantum optics such trajectories of the conditioned state are known as quantum trajectories [27].

The third chapter focusses on the derivation of the infinitesimal description of the time evolution of the conditional state by the Belavkin filtering equation. Two separate derivations of the filtering equations are given. In the first approach we simply differentiate along the trajectories for the conditioned state that we obtained in Chapter 2. A diffusive limit of the photon counting description enables us to incorporate the situation where instead of counting photons in the field we are performing a homodyne detection experiment.

The second approach uses the decomposition of a von Neumann algebra over its center. The observed process in the field determines a commutative algebra  $\mathcal{C}$  which is the center of its commutant  $\mathcal{A} := \mathcal{C}'$ . This commutant is the algebra of observables that are *not* demolished by the observation in the field. The central decomposition enables us to decompose the state restricted to  $\mathcal{A}$  over the possible paths the observed process yields. In this way we are able to condition the state on the observed path.

The central decomposition is an existence result. It doesn't show how to construct the decomposition. However, using martingale techniques familiar from classical filtering theory, it is possible to derive a stochastic differential equation for the conditioned state which is called the *Belavkin filtering equation*. Chapter 3 concludes with a recipe for the derivation of the Belavkin equation for a wide class of possible continuous time observations in the field.

In the fourth and last chapter we are not only interested in the time evolution of the state of an open system conditioned on the result of a measurement in its environment, but we also want to use the measurement result for controlling the state evolution. The objective is to keep the unknown state of a qubit fixed in time, i.e. to stop the decoherence.

We show that in a special case where the interaction with the field is such that the qubit only couples to commutative noise the above objective can be met. This special case is called *essentially commutative*. However in reality the qubit couples to two non-commutative noises. By putting the electromagnetic field in a squeezed state the variance of one of the noises increases while the variance of the other decreases. In this way we approach the essentially commutative case by stronger and stronger squeezing. We show that in the limit for the squeezing strength to infinity the unknown state of the qubit can again be kept fixed.

# Samenvatting

In dit proefschrift wordt de tijd evolutie van open quantum systemen bestudeerd. We concentreren ons op de tijd evolutie van de toestand van het systeem geconditioneerd op de uitkomst van een meting continu in tijd in zijn omgeving. Het doel is de afleiding van een stochastische differentiaal vergelijking voor de geconditioneerde toestand waarin het geobserveerde meetproces als een drijvende stochastische term voor komt.

De afleiding wordt uitgevoerd binnen het kader van *niet-commutatieve* of *quantum* kanstheorie. In deze veralgemeniseerde kanstheorie bestaat een niet-commutatieve generalisatie van Itô's stochastische calculus. De interactie tussen een open systeem en het gequantiseerde electromagnetische veld in de zwakke koppelings limiet wordt beschreven door een stochastische differentiaal vergelijking in deze niet-commutatieve zin. De stochastische differentiaal vergelijking voor de geconditioneerde toestand kan eruit worden afgeleid. Deze vergelijking wordt geïnterpreteerd als een niet-commutatieve generalisatie van de Kushner-Stratonovich filter vergelijking en heet de Belavkin filter vergelijking.

In Hoofdstuk 2 bestuderen we een foton detectie experiment. Het bestudeerde open systeem is hier een twee niveau systeem gedreven door een laser. Het systeem zendt fluorescentie fotonen uit in zijn omgeving, het electromagnetische veld. De uitgezonden fotonen worden continu in de tijd gedetecteerd. We conditioneren expliciet op een geobserveerde gebeurtenis door de corresponderende projecties om de toestand heen te zetten. Gebruikmakend van de processen geïntroduceerd door Davies [33] kan de tijd evolutie van het twee niveau systeem continu in de tijd afgeleid worden. Dit leidt tot een continue evolutie tussen de momenten waarop fotonen worden gedetecteerd en sprongen op de momenten waarop fotonen worden gedetecteerd. In quantum optica staan deze trajectorieën van de geconditioneerde toestand bekend als quantum trajectorieën [27].

Het derde hoofdstuk richt zich op de infinitesimale beschrijving van de geconditioneerde toestand door de Belavkin filter vergelijking. De filter vergelijkingen worden op twee verschillende manieren afgeleid. De eerste methode bestaat uit het eenvoudigweg differentieren langs een trajectorie van de geconditioneerde toestand. Een diffusieve limiet van de foton detectie beschrijving maakt het mogelijk om ook homodyne detectie experimenten in onze beschrijving op te nemen.

De tweede methode maakt gebruik van de ontbinding van een von Neumann algebra over zijn centrum. Het geobserveerde proces genereert een commutatieve algebra  $\mathcal{C}$  die het centrum is van zijn commutant  $\mathcal{A} := \mathcal{C}'$ . Deze commutant is de algebra van observabelen die *niet gedemoleerd* zijn door de observatie in het veld. De centrale ontbinding maakt het mogelijk om de toestand beperkt tot  $\mathcal{A}$  te onbinden over de mogelijke paden van het geobserveerde proces. Op deze manier kunnen we de toestand conditioneren op het geobserveerde pad. De centrale ontbinding is een existentie resultaat. Het laat niet zien hoe de ontbinding geconstrueerd kan worden. Gebruikmakend van martingaal technieken, bekend uit klassieke filter theorie, is het mogelijk om een stochastische differentiaal vergelijking voor de geconditioneerde toestand af te leiden, de Belavkin filter vergelijking. Hoofdstuk 3 sluit af met een recept voor de afleiding van de Belavkin vergelijking voor een grote klasse van mogelijke continue tijd observaties in het veld.

In het vierde en laatste hoofdstuk zijn we niet alleen geïnteresseerd in de tijd evolutie van de geconditioneerde toestand van een open systeem, maar we willen het resultaat van de continue tijd observatie ook gebruiken om de toestand van het systeem te controleren. Het doel is om een onbekende toestand van een qubit vast te houden in de tijd, dat wil zeggen de decoherentie tegen gaan.

We vinden dat dit mogelijk is in het geval dat de interactie met het veld zodanig is dat de qubit slechts koppelt met commutatieve ruis. Dit speciale geval heet *essentieel commutatief*. In werkelijkheid koppelt de qubit echter met twee onderling niet-commutatieve ruizen. Door het electromagnetische veld in een samengedrukte of gesqueezde toestand te nemen, kunnen we de variantie van een van de twee ruizen verkleinen terwijl de variantie van de andere wordt vergroot. Op deze manier kunnen we door sterker en sterker squeezen het essentieel commutatieve geval beter en beter benaderen. We laten zien dat in de limiet voor de squeezing naar oneindig de onbekende toestand van de qubit weer vast kan worden gehouden.

# Curriculum Vitae

Op 11 oktober 1976 werd ik, Luc Bouten, als tweede in het gezin van Piet Bouten en Mia Bouten-van Lier geboren te Helden. Ik doorliep de lagere en middelbare school te Panningen. Op de middelbare school, het Bouwens van der Boije college, werd mijn interesse voor wiskunde en natuurkunde gewekt. In 1995 begon ik aan de studie natuurkunde aan de universiteit te Nijmegen. Na het eerste studiejaar werd het zwaartepunt verlegd naar de studie wiskunde die ik vervolgens begin 2000 voltooide. In 2002 volgde de voltooiing van de studie natuurkunde. Tot mijn leraren behoorden Hans Maassen, Gert Heckman, Arnoud van Rooij, Ted Janssen, Thomas Rijken en Hubert Knops. Tijdens de studie was ik actief in een aantal universitaire raden en voorzag ik gedeeltelijk in mijn levensonderhoud door middel van het geven van werkcolleges.

Tegen het einde van mijn studie periode was ik voornamelijk geinteresseerd geraakt in quantum mechanica. In het bijzonder de mathematische zijde van de theorie, te weten spectraal theorie, kanstheorie en groepentheorie. Dit leidde in april 2000 tot de keuze promotie onderzoek te doen in het gebied van de quantum kanstheorie onder supervisie van Hans Maassen. Het promotie onderzoek bestond uit het toepassen van niet-commutatieve stochastische analyse op problemen afkomstig uit de quantum optica. Bijzondere aandacht ging hierbij uit naar Belavkin's quantum filter theorie. Kennis over quantum optica werd opgedaan tijdens een bezoek van drie maanden aan Howard Carmichael in Oregon VS. Aansluitend aan de voltooiing van het promotie onderzoek in april 2004 ben ik een aantal maanden post-doc geweest bij Slava Belavkin in Nottingham UK.
